This example of the impatience of Young contrasts with the eager personal appreciation of the algorithm of variations, in personal correspondence with Lagrange, then less than twenty years of age, by Euler, the greatest analyst of modern times, who had been himself engaged not very effectually, also on a physical basis, with the same range of problems. Of course, like all fruitful ideas, this principle reduces to a manageable simplicity once it is carefully systematised. Thus in arithmetic the supreme discovery of the Hindu philosophers, of a decimal scale, nine digits and a zero, with values determined by position, which now every child must learn, became, when passed on to the Western world through the Arabs, the starting point which rendered possible all progress in scientific calculation: and the doings of Pascal with a Torricellian vacuum tube on the Puy de Dôme promoted, perhaps completed, the consolidation into common form of the originally intricate Archimedean notion of fluid pressure. So too the mere notational scheme, or algorithm, of the variational method was a new jumping-off point for the mathematical physical analysis from which it had derived its inspiration: though the formal Calculus of Variations may be now wandering, in hope doubtless of ultimate consolidation, into complexities of functionality far removed from the smoothness which is sufficient for applications to atomic structures, unless as in quantal theory finite variations have to come into account. It is not surprising that Young was strenuous as to the superiority for educational purposes of logical study and illustration of general elementary principles taken over a wide range, prior to any undue premature absorption into specialisations for which a life-time would later be available. Thermodynamic concepts are an uncompleted modern instance of the transition from abstruse to elementary.

This is scarcely a suitable occasion to refer to

Young's extensive professional writings in the nascent sciences of medicine, which, perhaps not unjustly on the whole, have become neglected But his Croonian lecture, unearthed from them by Peacock, as delivered to the Royal Society soon after he had got the two volumes of "Lectures" off his hands, dealing with propagation in the arteries, in relation to the elastic pulsation through the perhaps perfect elasticity which surely must in the final causes of the organic world subserve some function, was a subject of pure hydraulic science in which he became, afterwards at any rate, very competent, with regard to which the last word has perhaps scarcely yet been said

Young was also closely and most effectively, yet as usual most concisely, concerned with the problems of geophysics, such as the tides and the figure of the earth, also with the statistical doctrines of insurances and the duration of life the former from his prominent official connexion with the Board of Longitude, the latter from his position as adviser to a life insurance society

A judgment, near the end of his life ("Biography", p 483) on the merits, as regards fruitful discovery, of various modes of intellectual training and investigation, is characteristic and perhaps still authoritative Dr Young's opinion was

> "that it was probably most advantageous to mankind, that the researches of some enquirers should be concentrated within a given compass, but that others should pass more rapidly through a wider range—that the faculties of the mind were then exercised, and probably rendered stronger, by going beyond the rudiments and overcoming the great elementary difficulties, of a variety of studies, than by *employing the same number of hours in any one pursuit*—that the doctrine of the division of labour, however applicable to material products, was not so to intellect, and that it went to reduce the dignity of man in the scale of rational existences".

His own astonishing scientific record, combined with very remarkable erudition in classical literature and general philology, and even with an assiduous cultivation of the Graces which in early life tended to make up for the austerities of a Quaker training, forms a remarkable example, surely nearly unique, of what can be achieved by mental industry, working largely inward on itself, and, one may add, it offers an incentive to the biographical exploration, as a chapter in the newer psychology, of the methods of thought of the pioneers in discovery, which in our nation has been none too keen

Infra-Red Photographs of Racial Types

By PROF C G SELIGMAN, F R S

MORE than a year ago, I received from Mr. L Bloch, of the Ilford Research Laboratories, a number of photographs—'couples' of dark-skinned subjects, all or mostly negroes—taken by ordinary and by infra-red light The difference in appearance is very remarkable on one hand the normal photograph, on the other such striking modification in colour of face and often pattern of clothing that a close examination is necessary to realise that the two prints are photographs of the same subject The most remarkable feature is that under the infra-red rays the normal dark skin of the negro appears of a waxy white pallor This is so striking and renders the two photographs of the same face so unlike each other that the suggestion was made that the infra-red photographs exhibited Mongoloid characters not obvious in the prints taken under normal conditions This, however, is not so, nor are any Mongolian characters observable in the infra-red prints of a much longer series of negroes and other 'coloured' men which have recently been submitted to me. The idea perhaps originated in the somewhat deep-set appearance of the eyes seen in many subjects in the infra-red prints Examination shows that this is an expression of the obliteration in the infra-red photographs of a considerable amount of the finer facial modelling, due largely to the loss of shadows and the finer gradations of tint Those who have not a series of photographs for reference will best appreciate the change by examining a photograph published by Dr S. O Rawling*, in which oranges, apples, tomatoes, and dark cherries, on a plate with a polychrome design, appear as if the whole were modelled in pale-coloured wax, no trace of the design being visible

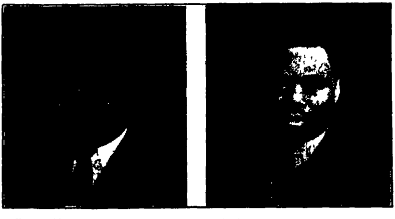

FIG 1 Photographs with panchromatic (left) and infra red (right) materials of a West African Negro (Temne) Note the waxy pallor of skin and lightening of irides, there is absence of the finer modelling but the unirrupted hairshafts show up through the superficial layers of skin

There are two interesting and curious features in these infra-red photographs of coloured men, though neither is of racial significance (Fig 1) Owing to the general lightening of colour, even the darkest eyes appear light, their irides as seen in the infra-red print appear of the same colour as blue-grey eyes in normal photographs The other peculiar feature is that it is often possible to trace the appearance of a beard and moustache in prints of clean-shaven men, due to the human skin having its maximum transmission in the region of the infra-red, so that the hair follicles with their contained hair shafts show up as darker shading

---

* "Infra-red Photography" (1933), p 34

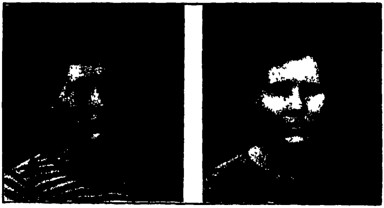

FIG 2 Photographs with panchromatic (left) and infra red (right) materials of a white girl (Nordic type), hair, very fair, eyes, blue grey complexion, very fair, wearing blue and white striped jumper

In the photographs of the white race, relatively few in number, some of these results are reversed (Fig 2) There is the same waxy pallor of the skin in the infra-red prints, and freckles are obliterated, but the eye colour changes in the opposite sense Instead of being lightened, eyes described as blue appear dark, so as to suggest deep hazel or medium brown On the other hand, in an infra-red print of a man whose eyes are described as brown, the irides are if anything a shade lighter than in the normal photograph, thus approaching the lightened colour of infra-red prints of the eyes of the dark races The normally dark eyes of a Japanese appear in the infra-red print about the same shade as the blue-grey eyes of a typical Nordic In Europeans the less dark shades of hair may appear considerably lightened, just as the leaves of trees present a white, almost frosted, appearance in infra-red photographs

To sum up the differences in the normal and infra-red photographs of the varieties of *Homo*, though striking at first sight, do not appear to present any features likely to be of use to the anthropologist, they are, indeed, of photographic rather than anatomical interest

Heavy Hydrogen[*]

By SIR J J THOMSON, O M, F R S

THIS lecture is on reminiscences connected with the Royal Institution, so that accounts of quite recent discoveries would not be within its scope There is one subject, however, which is now attracting a good deal of attention—heavy hydrogen—which satisfies both conditions, it is a reminiscence and it is connected with the Royal Institution In 1911 I gave a Friday evening discourse "On a New Method of Chemical Analysis" By this method each kind of gaseous particle in a vessel through which an electric discharge is passing produces its own parabolic curve on a photographic plate Thus if the vessel contained a mixture of hydrogen, oxygen and nitrogen, there would be six parabolas corresponding to the atoms and molecules of hydrogen, oxygen, and nitrogen respectively, along with others due to each of the compounds formed by these elements The mass of the particle which produces any parabola can be determined from the position of the parabola

Using this method, I detected the presence of a parabola which must have been produced by a particle of mass 3 (the mass of the hydrogen atom being taken as the unit) I obtained it first when the gas in the discharge tube was hydrogen prepared in the ordinary way, but its appearance was very capricious, and only occurred in a small percentage of the experiments I found, however, that if instead of using ordinary hydrogen, I used the gas given off by certain solids when bombarded with cathode rays, the (3) parabola appeared with great regularity The amount of the gas producing it varied with the nature of the solid bombarded, but there were few minerals or salts among those I tried which did not give traces of it, potash (KOH) is a very convenient source and a specimen of black mica given to me by Sir James Dewar gave an exceptionally large supply

I obtained the active gas also by deflagrating a very thin wire by passing a very large current through it, or even by raising a wire to bright incandescence This indicates that the bombardment by cathode rays does not manufacture the gas but merely liberates it from the solid

I made a very large number of experiments on the gas obtained in this way, the results of which were published in the *Philosophical Magazine* and summarised in my book "Rays of Positive Electricity" (Longman) One important property of this gas is that it can be stored after bombardment and tested long after it has been produced, showing that it is a stable gas and can exist in an uncharged state In fact, the persistence with which it clings to the walls of the discharge tube and the cathode makes experiments troublesome, as when once the tube has been used for this gas, it will continue, after the gas has been pumped out and replaced by another of a different kind, to show the (3) parabola , long sparking with oxygen in the tube is required to get rid of it

---

[*] From a Friday evening discourse delivered at the Royal Institution on February 9

I made many tests of the chemical properties of this gas and found that under them it behaved like ordinary molecular hydrogen Thus, for example, it disappeared after vigorous sparking in the presence of oxygen, or when passed slowly over red hot copper oxide , again like hydrogen it can pass through red hot palladium , and there was evidence that when an electric discharge was passed through it, some of its molecules were split up into a positively charged hydrogen molecule and a negatively charged hydrogen atom

Through the kindness of Lord Rutherford, I have had the opportunity of examining by the positive ray method samples of 80 per cent concentration of heavy hydrogen prepared by recent methods Very interesting photographs obtained with heavy hydrogen of less concentration have been published by Prof P Zeeman So far as I can see, the heavy hydrogen behaves in just the same way as the form of hydrogen obtained by bombarding solids With these high concentrations, so much heavy hydrogen adheres to the walls of the tube, that instead of trying to get rid of it by bombarding with oxygen, it saves time to make a new tube for each experiment Again, with the highly concentrated gas, I found, as Prof Zeeman had done, parabolas corresponding to H_4 and H_6 , in my early experiments a parabola (4) was frequently seen along with H_3 I ascribed it to helium and probably some of it was due to this source, but now I think part of it was due to H_4 , on a few occasions, too, I observed a line corresponding to H_6 The evidence seems to me to leave little doubt that the gas I called H_3 more than twenty years ago is the same as that which is now called heavy hydrogen

I said in "Rays of Positive Electricity" that from my experiments I suspected that there might be two kinds of H_3 , this surmise is confirmed by the fact that many chemists who have experimented on tri-atomic hydrogen have come to the conclusion that it has a life of only a minute or so, and can only exist when charged with electricity So far as I know, they all used hydrogen prepared in the usual way and not that obtained by bombarding solids , there is not the slightest doubt that the H_3 obtained in this way is stable and can exist uncharged

I think the effect of the solid is due to its adsorbing a mixture of gases including H_2 and H_3, and that when it is bombarded, relatively more H_3 than H_2 comes off from the adsorbed layers Thus the mixture that comes out is richer in H_3 than the mixture in the gas adsorbed by the solid

Obituary

SIR WILLIAM HARDY, F R S

THOSE who enjoyed Hardy's friendship, and even those who could hope for no more than occasional contact with him, will deeply feel the loss of a strong and vital personality radiating an influence which stimulated effort, cured discouragement and could reawaken flagging enthusiasms Hardy entered into everything he did with zest, and this seems to be the word which adequately describes his own attitude to life He met each successive experience with fresh interest, and brought his whole nature to the appreciation of whatever it offered of value His enjoyment of intellectual pleasures was itself almost sensuous, while his delight in the beauties of Nature, or in the appeal of fine pictures and music, was always mingled with—and, for him, intensified by—the intellectual reactions they evoked Life's minor pleasures appealed to him and he loved a good wine, and a good story, in the telling or the hearing, and he enjoyed both best in good company

Surpassing Hardy's many other enthusiasms was —as all his friends know—a passion for the sea and the adventures it provides for all good sailormen like himself Research stood high among his pleasures , he would literally smack his lips over some happy occurrence in a test tube, but probably the highest note in the gamut of his enjoyment was evoked by a boat with full sails, a spice of danger, and with the good ship answering to his hand on the helm

Some insistence upon this lusty side of Hardy's temperament is essential to any proper understanding of him as a man , but while he savoured all pleasures so keenly, his outlook was far indeed from that of the mere hedonist , his life was full of serious purpose, and no less full of accomplishment and service

I myself came first to know Hardy in 1898, when he was in his thirty-fourth year His scientific training had been that of a biologist, and at this time he was on Michael Foster's staff in the Physiological Laboratory at Cambridge He was, in particular, responsible for the teaching of histology to the advanced class, and had engaged in histological research He had published, alone and with others, several papers describing highly original work on wandering-cells, and *inter alia* on the nature of the attack of oxyphil blood cells on bacteria

Just before I became a member of the Cambridge staff, Hardy had convinced himself that current histological methods were employed with too little discrimination, and that many of the structures supposed to be characteristic of protoplasm were no more than artefacts produced by the action of reagents during the preparation of tissues for the microscope. Once assured that this might well be the case, he set himself with characteristic energy to investigate the matter. He was thus led to study aspects of the colloidal state in relations but then little known, and to deal with problems remote from his previous experience. He worked with the simplest of equipments, yet he rapidly brought significant facts to light. I was fortunate enough to occupy a room adjacent to his, and witnessed the progress of his research and the joy it gave him.

In 1899 Hardy published two classical papers "On the Structure of Cell Protoplasm" and "On the Coagulation of Proteid by Electricity". These titles do not convey the full significance of the work they describe. The clarity with which the existence of two types of colloidal dispersion was demonstrated, and the precision the work gave to the relation between electrolytes and colloids with its dependence upon ionic and micellar charges, together with other points of much importance described in these publications, made them extraordinarily influential. They stimulated work by scores of others and greatly accelerated the progress of colloidal chemistry.

Hardy retained to the end of his life an interest in this and kindred aspects of knowledge. He was specially curious as to the nature of the protein equilibrium in blood, and in the precise nature and meaning of the globulin fraction. Had he lived to deliver his address as president of the British Association, I believe that part of it, at least, was to be devoted to the results of his later thought on such questions.

The period of Hardy's researches to which I have been referring was of much significance to him. It led to his general interest in physical chemistry, and determined a direction for much of his later thought and work, his highly original dealings with the influence of chemical constitution on surface tension, for example, and the later developments which followed upon them.

In his earlier days as a physiologist, Hardy did not especially concern himself with metabolic phenomena, or with nutritional questions. The formation and management of the Royal Society Food (War) Committee, which fell to him as the biological secretary of the Society, awakened his interest in such matters and prepared him for the important work he was to do in later years as chairman of the Food Investigation Board.

Hardy's mind was but little trammelled by tradition, or even by the orthodox views of the day. His thought always worked on original lines. He was indeed no industrious reader of current scientific literature, seeking rather for the known facts whenever he wanted them for a specific purpose. This circumstance, and the great variety of his interests, together with his constant choice of the simplest possible technique in research, displayed qualities more often possessed by brilliant amateurs than by professional workers in scientific fields. One of the reasons for the success of his highly personal work was the freshness of mind that he brought to every problem, and the ingenuity with which he contrived his own simple, but adequate, experimental methods.

Hardy's genius had free play in the laboratory, and pure science has doubtless suffered from the fact that his latest years gave but little opportunity of displaying it there. One would be rash indeed, however, to suggest that he should have been spared from the administrative duties which he fulfilled so admirably and so greatly to the advantage of his country.

F. GOWLAND HOPKINS.

BY the death, on January 23, of Sir William Bate Hardy, at his home in Cambridge, in his seventieth year, science has lost a great captain and Great Britain a great public servant.

Hardy was educated at Framlingham and at Gonville and Caius College, Cambridge, where he was elected to a fellowship in 1892. He was Shuttleworth scholar in 1889, and Thurstonian prizeman in 1900. He was first and foremost a biologist, taking zoology in the Tripos, and then turning to physiology, and particularly to histology, a subject which he taught and in which he did research in Michael Foster's laboratory. To the end of his life he never lost his love of the microscope, and it is not many years since that he spent uncomfortable hours at a temperature of − 12° C. in one of the cold chambers at the Low Temperature Research Station, following through the microscope the process of freezing in gels.

From histology Hardy passed to the study of the colloidal state, a field then new and one in which he did pioneer work. No event in later life gave him more pleasure than to take part in the meeting at Cambridge in 1930 called by the Faraday Society to discuss the biological aspects of colloidal science. His scientific interests constantly broadened, and turning to the problems involved in action at surfaces, he entered the field of lubrication, and became a recognised authority on boundary conditions, contributing an article on the subject to the "Dictionary of Applied Physics". He was also Chairman of the Lubrication Research Committee of the Department of Scientific and Industrial Research.

The work for which Hardy was best known was, however, that which he did from 1917 onwards in the service of the Department of Scientific and Industrial Research as first chairman of the Food Investigation Board and as Director of Food Investigation. Here he found a new field that gave full scope for the exercise of his truly remarkable powers as leader and inspirer of a team of research workers, as advocate of the need for more science in industry and as apostle of co-operation in research between the members of the British Commonwealth of Nations. It was appropriate that the direction of the work should be in the hands of a biologist, for Hardy was never tired of stressing the logical priority of biology over engineering where the transport and storage of food is concerned

Research, to Hardy, meant essentially the untrammelled research of the university laboratory, carried out to satisfy that intellectual curiosity that he himself displayed so pre-eminently, and he never wavered in his conviction that no solution of a practical problem was worth while unless it was based on an adequate knowledge of the fundamental science that lay behind it, and therefore that it is the man with a sound training in academic research who is best fitted to unravel the practical problem and reach that solution The work described in the annual reports of the Food Investigation Board, and in the numerous other publications that came from his three research stations, the Low Temperature Research Station, the Torry Research Station and the Ditton Laboratory, bears witness to this insistence on fundamental research, and the success he had in solving practical problems and in gaining the confidence of the whole food industry were his complete justification Such achievements as the gas-storage of fruit, the long-range transport of chilled beef and the brine-freezing of fish were not fortuitous, but rather the inevitable outcome of much patient work of a fundamental character

Hardy, however, was not one-sided While he unerringly picked men capable of academic research, and saw that they had the opportunity and the means of doing it, he equally insisted that they learn the practical details of the industry they served, for he knew that only so could they gain the confidence of industry and, when the time came, apply their academic knowledge to the greatest advantage.

To-day, when the storage and transport of foodstuffs is so rapidly being put on a sound scientific basis, and when new developments are taking place in all directions, it is fascinating to go back and read the original memorandum which he, Sir John Farmer and Sir William Bayliss prepared in 1917 for the Advisory Council for Scientific and Industrial Research One marvels that one man in so few years could achieve so much, and one realises Hardy's tremendous power The original membership of the Food Investigation Board was strong, it comprised Sir Kenneth Anderson, Sir Joseph Broodbank (Hardy's successor in the chair), Sir Walter Fletcher, Sir Thomas Mackenzie, Sir Richard Threlfall and Prof. T B Wood What they thought of him may be illustrated by a remark of Threlfall's—"Hardy, you must treat us like your umbrella—to be kept rolled up out of the way, and brought out only when a storm comes"

Hardy's other great interest in later years was marine research. On his advice, the Development Commissioners appointed an advisory committee for fisheries research under his chairmanship This committee drew up a programme which was adopted by the Commissioners, whilst at the same time the committee was made permanent and for nine years Hardy remained its chairman The breadth of his view and his practical knowledge, as well as his personal familiarity with the special difficulties of work at sea, were of inestimable value His penetrating understanding of their work and his constant help and sympathy were a source of inspiration to the biologists and hydrologists engaged in the investigations. Especially he realised that no practical results could be looked for until a large amount of fundamental research had been done, not only on the life-histories of the marketable fishes themselves, but also on the physical and biological conditions under which they lived Not only the changes in the chemical constitution of the sea-water from season to season and from year to year, the variations in tides and currents, the influence of light, must be known, but also the inter-relations of the whole flora and fauna which form the fundamental food of the fishes require detailed study. This work throughout had his earnest support and sympathy

Many honours came Hardy's way, and he wore them with the simplicity that characterised his whole life In the academic sphere, he was elected a fellow of the Royal Society in 1902, served as secretary from 1915 until 1925, and was Royal medallist and Croonian and Bakerian lecturer of the Society Oxford conferred on him the honorary degree of D Sc, and Aberdeen, Birmingham and Edinburgh that of LL D In 1931 he was invited to the United States of America and delivered the Abraham Flexner lectures at Vanderbilt University At the time of his death he was president of the British Association for the Advancement of Science In the wider sphere he was a member of the Economic Advisory Council, and of the Advisory Council for Scientific and Industrial Research, president of the British Association of Refrigeration, a Trustee of the National Portrait Gallery, and a member of the Governing Body of Charterhouse and of the Leverhulme Trust Committee He was knighted in 1925.

Hardy's lay interests were as varied as his scientific interests Salt-water sailing was a passion with him, and he owned a succession of small yachts which he sailed regularly He was a good naturalist, with a wide and intimate knowledge of plants and birds Music and archæology also claimed his time Bridges' "Testament of Beauty" became his constant companion on its publication, and he was an enthusiastic 'Janeite'

Hardy was a big man in every way Big in body, with a fine head and big, capable, sensitive hands—craftsman's hands, instinctively one knew him incapable of anything small or mean With this bigness went utter simplicity and honesty of purpose, an inexhaustible fund of enthusiasm and great warmth of heart, such a combination was irresistible

He married in 1898 Alice Mary, daughter of Mr G B Finch, who survives him, with his son and his two daughters

News and Views

The King of the Belgians and Progressive Science

A GREAT figure of the War has passed away with the death on February 17 of Albert I, King of the Belgians, at the early age of fifty-eight years For nearly twenty-five years he guided his people faithfully, carrying them with him through the War years, urging them on and directing their progress during the not less uncertain years following the Peace of Versailles His work in the political field has been set forth in many places We are concerned here with his interest in science and scientific research, of which he was a convincing advocate He played an active part in the development of scientific institutions in Belgium. The protection of flora and fauna, particularly of tropical regions, early attracted his attention, and in 1909, after a visit to the Congo, he put forward a plea for protective measures which culminated with the creation, in 1929, of the Parc National Albert, a nature reserve of nearly 1,400 square miles So recently as 1932, King Albert visited the Kivu Park with Prof V Van Straelen in order to see for himself the effectiveness of the protective measures

KING ALBERT's name will also be associated with the "Fonds national de la recherche scientifique" in Belgium. Speaking at the one hundred and tenth anniversary of the well-known Cockerill iron and steel works at Seraing in the autumn of 1927, the King declared emphatically that pure science is indispensable to industry, and that the nation which neglects science and the savant is marked for decadence The appeal had an immediate effect A great gathering was held at the Palais des Académies, Brussels, which was attended by the King, Ministers of State, and representatives of industry, finance, politics, science and the universities Again King Albert made a powerful plea for science, poor herself but the creator of riches, for security and independence for scientific workers in order that they might devote themselves entirely to their studies, then he announced the creation of the "Fonds national", to which he invited industrial and financial interests to contribute King Albert was well known in Great Britain, and on a recent visit, his enthusiasm for scientific research led him to spend an afternoon examining the treasures of the Royal Institution, after which he enjoyed a 'laboratory' tea with Sir William Bragg and members of the staff, and watched some experiments with liquid air in illustration of the late Sir James Dewar's work.

History Made in Germany

IN another column of this issue of NATURE (see p. 298) is a translation of an official circular, issued to all education authorities in Germany by the Minister of the Interior, on the teaching of prehistory and history, which contains 'directive ideas' to be followed in historical instruction and to serve as a standard in the adoption of textbooks. The directions in the circular deal first with certain 'points of view' which "hitherto have been considered inadequately, if at all", and secondly, give an outline of the manner in which the theory of Nordic racial and cultural supremacy is to be applied in dealing with the course of events from the earliest times to the present day. The study of 'race' and 'culture' are to be made to subserve the German nationalist idea, while the heroic legends will quicken the emotional appeal of leadership in present-day 'national assertion'. From the point of view of prehistoric and historical science, the contents of this document are astonishing It is scarcely necessary to point out that the racial and cultural unities which are to be made the basis of the modern German nationalist State are non-existent in point of fact, but rest on misstatement or misinterpretation. If, however, these 'directive ideas' appear too biased, too frankly propagandist, to call for critical examination from the point of view of ethnology, archæological science, or history, they must none the less be regarded as symptoms of a grave condition of thought The circular suggests that Germany is prepared to abandon all standards of intellectual honesty in pursuit of a political ideal, which, it may be noted, it is hoped to impose on all 'Nordic' peoples

Prof. Harold C. Urey

PROF HAROLD C UREY, of Columbia University, has been awarded the Willard Gibbs medal of the Chicago Section of the American Chemical Society for his discovery of 'heavy water' Prof Urey, at the age of forty-one years, is the youngest man ever to receive this honour He was born in Walkerton, Ind , on April 29, 1893 In 1917 he was graduated from the University of Montana with the degree of bachelor of science in zoology In 1923 he received the Ph D. degree in chemistry from the University of California He received an American-Scandinavian fellowship for research in 1923–24, studying under Prof N Bohr at Copenhagen He was assistant in chemistry at Johns Hopkins University in 1924–29, and has been associate professor of chemistry at Columbia since 1929. The Willard Gibbs medal, founded by William A. Converse in 1911, was named after Josiah Willard Gibbs, professor of mathematical physics at Yale University from 1871 until 1903, who, although not primarily a chemist, did much to advance the science of chemistry It is awarded annually by the Chicago Section of the American Chemical Society to a scientific worker "whose work in either pure or applied science has received worldwide recognition" The award is determined by a national jury of men of science. The first Gibbs medallist was Svante Arrhenius of Sweden.

Constitution of the Stars

THE fourth Rickman Godlee lecture was delivered at University College, London, by Sir Arthur Eddington on February 16. Lord Dawson of Penn presided, and paid a tribute to Rickman Godlee's great pioneer work in the surgery of the brain and to his wide range of interests in scientific work and in affairs. Sir Arthur Eddington took as his subject the "Constitution of the Stars". He reminded the audience that the problem of the constitution of the stars was first set forth in a paper, with a somewhat strange and comprehensive title, published by Lane in 1869. Since then, many attempts have been made to compute the temperatures existing deep inside the huge celestial furnaces. Thus, in the case of the sun, whilst the measured temperature of the photosphere is six thousand degrees, the computed temperature at the centre is twenty million degrees. This central region is now considered to be constituted of swarms of protons and stripped atoms moving at speeds of hundreds of miles per second, of swarms of electrons moving at ten thousand miles per second, and an enormous quantity of X-radiation which is mainly responsible for the permanent shape of the sun. Because of its nature, the energy of this radiation can only leak away slowly, by a stepping-down process.

OWING to excessive ionisation, the average mass per particle in the middle of the sun is only two units, unless a considerable quantity of hydrogen is present. We have to know the average mass per particle in order to calculate the temperature at the centre. Sir Arthur said that he first made a reservation concerning the effect of hydrogen in 1927. It is now possible to measure the mass and the absolute brightness of a star and to say with some degree of certainty how much hydrogen it contains. In 1934, a further reservation is necessary because of the discovery of the neutron, for if neutrons were present to the extent of five per cent in the constitution, the material heat of the sun would be rapidly lost by conduction. However, it is felt that the properties of neutrons are not yet sufficiently established to make predictions, and, in any event, they can probably only exist inside atomic nuclei when near the centre of the sun. Sir Arthur also discussed the significance of recent experiments on artificial disintegration, which suggest a means by which the energy of the sun is replenished, namely, by the absorption of protons in atomic nuclei. This means that the temperature of the centre cannot rise much above ten million degrees so long as appreciable amounts of hydrogen are present.

REFERRING to the "gaseous mass" postulated in Lane's paper, Sir Arthur Eddington pointed our that the sun obeys laws deduced for perfect gases, because of the huge compressibility of the stripped atoms inside the furnace. Densities some thousands of times greater than that of the earth are thus possible, and, indeed, are actually found to exist, for example, in the case of the dark companion of Sirius. Moreover, an application of the Pauli exclusion principle shows that such extremely dense matter must be cold, as is the companion of Sirius. Thus, although we seem farther away than ever from a solution of the problem of the evolution of the universe, Sir Arthur suggested that, since we are now able to formulate problems which were not even suspected ten years ago, we can more adequately measure our progress by the problems we are able to present for solution rather than by those we are able to solve.

Oil from Coal in Great Britain

OIL from coal was the subject of a debate in the House of Commons on February 8, when the British Hydrocarbon Oils Production Bill was read for the second time. The Bill proposes to give a preference of 4*d*.-9*d*. a gallon on oil derived from British coal, peat and shale. The exact amount of the preference will depend on the customs duty payable on imported material, or on the difference between it and any excise duty. The duration of the preference will depend on its amount: at the minimum rate of 4*d*. a gallon it will operate for nine years, or, at 9*d*. a gallon, for four years. The Secretary for Mines (Mr. E. Brown) reported that the Government announcement of policy has already been followed by industrial developments. Imperial Chemical Industries have started the erection of a plant at Billingham for the annual production of 100,000 tons (30,000,000 gallons) of motor spirit by the hydrogenation of coal. A substantial increase is also shown in the amount of benzol obtained last year from gas works and coke ovens, as well as in the quantity of motor spirit from shale oil and low temperature carbonisation processes. More than 10,000 men have been put into employment already in connexion with the Billingham plant, and, in operation, it will absorb 1,280 men, and, in addition, some 1,200 miners for the production of 350,000 tons of coal a year. The actual cost to the Treasury of the production of 100,000 tons of oil under the new preference will, it is estimated, be about £1,000,000.

Economic Issues in Hydrogenation

THE debate on the Bill referred to above brought forward a number of criticisms of the scheme. The opinion was voiced that the enterprise should be State-owned and directed, and also that the developments should be planned so as to assist the more depressed mining areas. It was also pointed out that hydrogenation has been in progress for a number of years in Germany, where very cheap lignite is available. In spite of a similar preference granted in that country, the synthetic petrol manufactured there in 1933 was less than the amount which is to be produced in Great Britain under the new scheme. Both the technical and the economic success of the process were, in fact, questioned. The motor-car industry is also faced with developments in heavy-oil engines of the Diesel type, which may in time displace light-oil engines and lessen the demand for petrol. A strong case was put forward, however, for the founding of this new industry as a means of utilising British coal resources more efficiently, and also for the covering of the requirements of national defence.

Research on Foul Brood Diseases of Bees

BY co-operation between the bee keepers of England and the Agricultural Research Council, financial arrangements have been made to carry out at the Rothamsted Experimental Station, an investigation of foul brood diseases of bees, which have hitherto caused considerable trouble and loss. Dr. H. L. A Tarr has been appointed investigator. Dr. Tarr is a graduate of the University of British Columbia and McGill University, and since 1931 he has been working at bacteriological problems in the Biochemical School at the University of Cambridge Foul brood diseases were investigated in England nearly fifty years ago by Cheshire and Cheyne, and in more recent years by workers in the United States, Canada and on the Continent, but in spite of all that has been done, little is known about the cause of the diseases and still less as to how to avoid or cure them The bee keepers, through the British Bee Keepers Association, have now agreed to raise half the money necessary for the investigations, and the Agricultural Research Council has undertaken to contribute the other half As a result, a sum of £500 a year is now available for the study of foul brood It is hoped that the work will continue for a period of at least three years, starting early in March 1934 under the general direction of Dr C. B Williams, head of the Department of Entomology at Rothamsted, with the co operation of Mr. D M T. Morland, apiarist. Some of the more purely bacteriological side of the work will be carried out at the Lister Institute in London. Rothamsted Experimental Station will be advised on the practical side of the work by a small expert committee of bee keepers Further contributions towards the cost of the investigations will be welcome

National Importance of Scientific Research

REVIEWING the organisation of industrial research in Great Britain and other countries in an article in the *Draughtsman* of December entitled "Research and Industry", Mr G Windred concludes that we are at present by no means in a leading position, due perhaps to the curtailment of research expenditure in almost every direction, consequent upon the reduction of Government expenditure and the unwillingness of commercial organisations to spend capital. Mr. Windred states that industry, as a whole, is not prepared to apply scientific research methods until their possibilities have been clearly demonstrated "Such demonstration can be effected only with the aid of research experience which must involve considerable expenditure, such as other countries have in general been willing to provide". The author reminds us that in the various departments of pure science, Great Britain holds a premier position which must prove of great assistance in the work of applying scientific principles to industrial improvement, and pleads for increased opportunities for industrial research. Assuredly, in this era of world-wide industrial progress, we can no longer afford to suffer the accusation that, however important are our fundamental discoveries in pure science, we yield pride of place to others in their application.

PUBLIC interest in the national importance of scientific research has recently been stimulated in Germany by a series of publications which are intended to awaken all classes to a realisation of the material benefits involved, and to counteract the tendency for too stringent economy in scientific work These publications, which are written in non-technical language, are sponsored by scientific and educational associations of high standing. In the United States there are said to be more than 1,500 well-established research organisations, and the expenditure of American industry in support of these research laboratories has been assessed for the year 1931 at no less than 235 million dollars. The activities of the Mellon Institute of Industrial Research of the University of Pittsburgh are too well known and appreciated in Great Britain to require more than a passing reference As regards Russia, Mr Windred has no doubt that the plans for scientific reconstruction in that country have the strongest scientific arguments in their favour. He devotes considerable attention to the work of the British Science Guild, which was founded in 1905 by Sir Norman Lockyer. The following statement, which the Guild has included in the announcement of its aims, objects and activities, is so manifestly pertinent to the conditions of to-day that it deserves the widest possible publicity . "The most urgent practical need to-day is the promotion of the spirit of unity among all classes through the alliance of Science, Invention and Labour, working as a single force for national development and common welfare Science discovers ; Invention applies ; Industry produces. No nation can occupy a place in the van of modern civilisation unless the three legs of this tripod form strong and secure supports for all its constructive activities".

Recent Advances in Microscopy

MR CONRAD BECK, in his presidential address to the Royal Microscopical Society on January 17, pointed out that the resolution of the microscope had reached at least 100,000 lines to the inch in the middle of last century, and this limit was extended by steady advances to nearly 140,000 by the end of the century, but the limit is now placed at a figure that is less than 1/300,000 in In referring to dark ground illumination, he stated that while it was used with low and moderate powers almost from the time achromatic microscopes were first made, it is only in recent years that the refined apparatus required to use it with high power lenses has been produced. He remarked that this technique does not render differential staining less important and expressed his satisfaction that the Council of the Society has appointed a committee to study the stains and reagents used for microscopic research, and he suggested that, in addition to other matters, consideration should be given to the introduction of differential stains, particularly designed for dark ground illumination. As an example, he cited the anthrax bacillus which, stained with methylene blue, appears blood-red by dark ground, and hence there might be stains which would differentiate structure viewed by this means to a greater extent than can be done with transmitted light.

Dark ground illumination has not only doubled the resolution of the microscope, but also has more than doubled the visibility of small objects The use of quartz lenses corrected for ultra-violet light involves photographing images, but as no direct method of focusing is satisfactory an indirect method has been devised. An object-glass was made suitable for visual observation with approximately the same focal length as the quartz lens and a perfect method of interchanging the two has been worked out. A slow motion fine adjustment that can be moved a definite amount with certainty to compensate for the small predetermined difference in focus, and capable of moving the lens with an accuracy of $\frac{1}{30}\mu$, is the chief factor in the success of the technique In concluding, Mr Beck referred to the high cost of the apparatus necessary and asked whether this type of work should not be carried on in endowed institutions, just as is modern astronomical work.

Boilers for Critical Pressure

A notable paper was read to the Institution of Electrical Engineers on February 15 by F Ohlmuller on the Benson boiler and its development for use in power stations Dr. Mark Benson came to Great Britain some years ago and with the help of the English Electric Co carried out experiments on a 500 h p. steam turbine built for the purpose of working with steam evaporating at the critical pressure (3,200 lb. per sq in) At this pressure the latent heat of water is zero The water being heated to the critical temperature (706° F) turns completely and instantaneously into steam. Unlike ordinary boilers there is no separation of steam from water. In the present design of the boiler, dry steam is produced with certainty in steel tubes. At the outset, many difficulties had to be overcome. The manufacturing rights are now the property of the Siemens-Schuckert Co of Berlin. They have overcome the trouble experienced with the tubes at Rugby. They now manufacture tubular boilers for use both at the critical and at subcritical pressures. Tests showed that the burning out of the tubes was due to the precipitation of salts contained in the feed water on the parts of the tubes where the water changes into steam. This occurs in the zone where evaporation terminates and superheating begins. The remedy is to change the zone of deposit to a region of lower flue-gas temperature

Hitherto the pressure in steam boilers has been regarded as a constant dependent on its construction. The Benson boiler operates with high efficiency not only at the highest possible pressure and at lower pressures, but also with varying pressures, and this seems to open a new field of usefulness. In warships, for example, the fuel consumption must be low at cruising speeds but for temporary maximum speeds, amounting to a multiple of the cruising speed, the quantity of fuel consumed is of minor importance. For cruising purposes, therefore, a relatively low pressure of 300 lb. per sq. in. may be used, and by increasing the pressure, ten times the power output can be obtained. With merchant ships a uniform speed is usually required, but for manœuvring in ports and estuaries a variation of the boiler pressure offers the most economical means of varying the ship's speed. The Benson boiler seems very useful for many purposes. For stationary steam plants with widely variable load (peak load stations) and locomotives, it can be operated at pressures varying with the load. A cheap and simple turbine only is required and an approximately constant thermal efficiency at all loads is obtained. In erecting many generating stations, industrial plants and thermal stations, difficulties often arise owing to the uncertainty about the future load With this new boiler an increase in the output whenever necessary can be obtained simply by raising the pressure of the steam, as the cost of adapting the turbine and piping to the new conditions is small

Negro-Indian Crosses in Mexico

Spanish settlers in Mexico and Central America appear to have taken an interest in the results of racial intermixture from early days Several series of paintings in oils of seventeenth century date are in existence, of which each picture depicts a family of mixed breed, both parents and children, Spanish-Indian, Spanish-Negro and Indian-Negro, the characters being faithfully presented. The number of pictures in each series is usually five or six. One of the best is, or was, in the possession of the Hulse family, the tradition being that it was part of the dower of Dorothy Woodrow, who married the first baronet towards the end of the seventeenth century. The series was supposed to have been captured from the Spanish in a naval engagement; but some at least of the pictures obviously must be of later date. It is interesting to note that the evidence of cross-breeding as shown in physical characters is still to be observed in the descendants of these early admixtures.

A joint Mexican and Italian expedition which is now engaged in observation of the natives of the coast of Guerrero, southern Mexico, reports, according to a communication issued through Science Service, Washington, D.C , that not only do the inhabitants of this area show the traces of their descent from the Negro blood of colonial days in a complexion which is appreciably darker than that of the general run of the Indian population, but also the two communities of Indian and Negro blood hold aloof from one another, and show marked differences in temperament and custom The natives themselves make use of no less than five terms to distinguish the degree to which the hair of the head shows the Negro character. The tight-kinked African hair is called 'cuculuxtle', an Aztec Indian word; hair tightly curled in ringlets, which shows a slight dilution of Negro blood, is 'chino'; the looser waves produced by a greater proportion of Indian blood is 'crespos'; and the 'pelo quebrado', 'broken hair', is Indian hair which is only slightly waved.

Institute of Plant Industry, U.S.S.R.

A list of publications of the Institute of Plant Industry, U.S.S.R. from 1908 until 1931, compiled by Windelbandt (Bibliographical Contributions No. 2, Institute of Plant Industry, Leningrad) supplies a long-felt want amongst applied botanists. Reorganisation and changes of title, which have at various times affected the Institute and its publications, have made it difficult for many to check the completeness of their sets of publications. The Institute of Plant Industry, as it is known to-day, uniting the activities of numerous research institutions and field stations, has evolved from the Bureau of Applied Botany founded in 1894. The serial numbering of the original *Bulletin* is maintained, and this list takes the *Bulletin of Applied Botany, Genetics and Plant Breeding* to the point where it is split up into three series, one of which is subdivided into thirteen sections. The list is published in Russian and in one other language, generally English or German, according to the language in which the summary or translation is issued. While German was used up to 1914, most translations now appear in English An indication is also given in cases where the articles appear only in Russian, and also if the number is out of print. The list, which includes supplements and seed catalogues, has a wide interest. A large amount of work of a fundamental nature is included as well as the ordinary routine crop experimental work The crops include tea, oil- and rubber-bearing plants, etc , in addition to the usual crops found in Europe

Pelotherapy

Peloid, from the Greek πηλος (= mud), was adopted by the International Society of Medical Hydrology at its recent annual meeting in Switzerland as a generic name applicable to any naturally produced medium such as is used in medical practice as a cataplasm for external treatment. Such media are known in the various countries as boue, fango, gyttja, liman, moor, mud, peat, schlamm, etc , these names being used in confusion for both specific media and in a generic sense The new word, with its derivatives *pelology* and *pelotherapy*, will avoid this confusion and allow the local terms to be defined and used in their restricted sense The Society appointed an International Standard Measurements Committee, with Dr. S Judd Lewis as chairman, to investigate the properties of these peloids, and they are now classified into groups as (1) purely mineral , (2) alluvial and marine, characterised by the organic matter being of the thallophyte type, as is the case with those permeated with algal, diatomaceous, bacterial and similar structures: (3) an intermediate group of terrestrial peloids; (4) those of mainly vascular-vegetable origin, such as moors or peats from (*a*) mosses, (*b*) phanerogams, etc , (5) peloids mainly of marine vegetable origin; (6) peloids derived from petroleum deposits; and a detached group, 10, for 'artificial' or 'factitious peloids' The Committee has now to consider the components—saline, mineral (geological), organic (for example, humus), vegetable structures, micro-organisms, etc.; the physical properties—heat conductivity, heat capacity, plasticity, colloidal properties, radioactivity, etc ; and the clinical indications.

First International Congress of Electro-Radio-Biology

WE have received a notice that the International Society of Radio-Biology, having its headquarters in Venice, is preparing to organise the First International Congress of Electro-Radio-Biology, which it is hoped will take place in that city in September next. It may be that there is room for an international society dealing with this subject, but a very considerable part of the programme would appear to come within the purview of the International Congress of Radiology which meets in Zurich in July of this year. It appears from the memorandum issued that a number of representatives from different countries will give lectures and speeches at this proposed Congress, but we regret to say that we do not see the name of a single British representative; but other names, it is stated, will be added in successive communications, so that should the Congress take place, we hope to see some representatives from Great Britain take an appropriate part Those who desire more detailed information are invited to apply to the temporary head office of the International Society of Radio-Biology, addressing their correspondence to . Dr Giocondo Protti, Venice (Italy), Canal Grande—S Gregorio 173

A Map of the British Isles, 1603

IN the University of Göttingen there is apparently the only copy of a map of the British Isles published in 1603 by John Woutneel and engraved by William Kip. It is a large sheet cut into four and came into the possession of the University in 1735 A photostat of the map is now in the British Museum In the *Geographical Journal* of December, Mr. E Lynam gives some account of this map. Woutneel was a Flemish bookseller living in London and Kip was a Dutch engraver who engraved the thirty-four maps in Camden's "Britannia" (1607) England and Wales on Woutneel's map are copied from the second edition (1594) of the Hondius map and show different spellings and more names, some of which are taken from Saxton Scotland is copied from the Ortelius map of 1573 Ireland is based mainly on the 1594 map, but seems to contain some original work Mr. Lynam does not believe that this map was the general map of an atlas that embraced the anonymous county maps of 1602–3, which do not appear to be Kip's work. It is not a good map Mistakes are numerous and there is evidence of hasty copying but it is notable for the marking, not always correct, of battlefields, and its fine engraving. It will be of interest to discover if other copies are in existence.

Biochemical Research in India

THE Society of Biological Chemists, India, now in its third year, publishes annually "Biochemical and Allied Research in India"; the number for 1932 has recently been issued. This publication takes the form of a review of research work published during the year, by Indians and other workers in that country, usually in Indian journals. The subject matter is dealt with under the following headings:

enzymes, agricultural chemistry, food and nutrition of farm animals, dairy chemistry, general microbiology, vegetable physiology, phytopathology, pharmaceutical and medicinal chemistry, nutrition and vitamins, and the chemistry of sanitation with special reference to sewage and to water. The journal is edited for the Society by a committee and the names of the reviewers are appended at the end of each section Upwards of three hundred papers are referred to, indicating the vitality of research into biochemical problems in India. Although many of the results obtained are chiefly applicable to conditions in that country, much of the work is of a wider interest and must be taken into consideration by workers on similar problems in other parts of the world This journal forms a ready means of keeping in touch with biochemical research in India.

Birds of Hawaii

A REPORT that Hui Manu, the bird society of the Honolulu and Sandwich Islands, has decided to undertake a scheme for breeding and distributing many of the vanishing birds of the Hawaiian archipelago, is of interest, for these Pacific islands are perhaps the most isolated of all oceanic groups Rothschild ("Avifauna of Hawaii and nearby Islands", 1893–1900) records 47 species from Hawaii, 34 of which breed, and from the neighbouring islands, Laysan 40, Kawai and Nishan 41, Oahu 28, Molokai 21, Maui 26 and Lanai 18. The introduction of many birds foreign to the islands, and particularly the European house-sparrow (*Passer domesticus*) now one of the commonest birds of the islands, has seriously affected the native avifauna, while Wetmore (*Nat Geog Mag.*, 18, 77; 1925), in a survey of the bird-life of the group, recorded considerable damage from the introduction of rats and rabbits It was in 1909, through the interest of President Roosevelt, that the Hawaiian Bird Reservation was set up under the control of the United States Department of Agriculture. Amongst the fifty odd species recorded in the group, Heilprin states all the passeres and five of the aquatic and wading birds are peculiar

North East Coast Institution of Engineers and Shipbuilders

AT a meeting of the Council of the North East Coast Institution of Engineers and Shipbuilders held on February 12, Mr Summers Hunter, formerly chairman of the North-Eastern Marine Engineering Co., Ltd, presented the warrant of the College of Arms granting armorial bearings to the Institution. Mr Summers Hunter has been connected with the Institution for nearly fifty years as a president, and also an honorary fellow He is also a past president of the Institution and of the Institute of Marine Engineers. The arms of the bearings are an ancient ship with sails set, surmounted by a tower triple-towered between two wheels, symbolical of engineering. The crest is a sun encircled by a chain, representing the harnessing of the forces of Nature for the use of man. The motto is "By Science, Industry and Honour".

Announcements

THE first educational tour of the Institute of Metals will be made to Belgium on April 8–14, when student members will have an opportunity of visiting six large metallurgical establishments and of seeing something of Brussels (including its University) and Bruges. The cost per head will be £6 10s. Students desirous of participating should communicate before March 12 with the Secretary, Mr. G Shaw Scott, 36 Victoria Street, London, S.W 1.

AT the annual general meeting of the Quekett Microscopical Club held on February 13, the following officers were elected for 1934–35 *President*, J Milton Offord; *Vice-Presidents*, C. D Soar, J Ramsbottom, E A Robins and J T Holder, *Hon Treasurer*, C H Bestow; *Hon Secretary*, W S Warton, *Hon. Reporter*, A Morley Jones, *Hon Librarian*, C H. Caffyn, *Hon Curator*, C. J Sidwell, *Hon Editor*, W P Sollis; *New Members of the Committee*, Percy C. Palmer, C Harvey, E J. Stream, A W Sheppard.

WE much regret that the name of the author of the article entitled "Reference Chart for the Apparent Motions of the Sun, Moon and Planets" in NATURE of January 6, p 33, was spelt incorrectly The author's name should have been printed "Dr B. K. Vaidya"

THE encyclopædic "Handbuch der biologischen Arbeitsmethoden" edited by Prof. Abderhalden includes, among its most recent parts, one written by Dr. F. Zacher. This instalment deals with the behaviour and development of insects affecting stored products It can be recommended as an up-to-date work of reference written by a leading European authority on the subject.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned.—A chief librarian for the County Borough of Southport—The Town Clerk, Town Hall, Southport (Feb 26). A principal assistant (technical) in the Chief Engineer's Department of the London County Council—The Clerk of the Council, The County Hall, Westminster Bridge, London, S E (March 2) A City engineer and surveyor to the City of Bradford – The Town Clerk, Town Clerk's Office, Bradford (March 10) An assistant keeper on the higher technical staff of the Science Division of the Science Museum—The Director, Science Museum, South Kensington, London, S.W 7 (March 10) A vice-principal and head of the Mathematics Department at the Leeds College of Technology—The Director of Education, Education Offices, Leeds (March 10). A mechanical engineer as assistant to the chief engineer of the Dublin Port and Docks Board—The Secretary, Port and Docks Office, Dublin (March 14) Two lecturers to share the teaching of mathematics, physics, biology, chemistry and geography at the Cambridge Training College for Women—The Principal (March 14). A chief engineer at the British Drug Houses, Ltd., Graham Street, London, N.1—The Managing Director.

Letters to the Editor

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

International Status and Obligations of Science

IN his Huxley Memorial Lecture, extracts from which were published in NATURE of December 23, Prof A. V. Hill has made detailed statements regarding the treatment of German scientists by the National-Socialist Government. These statements are not in accordance with the truth As a scientist, whose duty it is to discover and proclaim the truth, I venture to place on record the following facts as against the inaccurate assertions of Prof Hill

The National-Socialist Government has introduced no measure which is directed against the freedom of scientific teaching and research, on the contrary, they wish to restore this freedom of research wherever it has been restricted by preceding governments Measures brought in by the National-Socialist Government, which have affected Jewish scientists and scholars, are due only to the attempt to curtail the unjustifiable great influence exercised by the Jews. In Germany there were hospitals and scientific institutes in which the Jews had created a monopoly for themselves and in which they had taken possession of almost all academic posts There were in addition, in all spheres of public life in Germany, Jews who had come into the country after the War from the east This immigration had been tolerated and even encouraged by the Marxist government of Germany Only a very small part of the 600,000 Jews who earn their living in Germany has been affected by the National-Socialist measures No Jewish civil servant was affected who had been in office before August 1, 1914, or had served at the front for Germany or her allies or whose father or son had fallen in the War.

Prof. Hill asserts that something more than a thousand scholars and scientific workers have been dismissed, among them some of the most eminent in Germany In reality not half this number have left their posts, and among these there are many Jewish and slightly fewer non-Jewish scientists who have voluntarily given up their posts Examples are the physicists Einstein, Franck, Born, Schrödinger and in addition Landau, Fränkel (mathematician), Fränkel (gynæcologist), Prausnitz (hygienist), and others. Prof Hill says that there are 100,000 people in concentration camps in Germany and that they are there only because they wished to have freedom of thought and speech The truth is that there are not even 10,000 in the concentration camps and they have been sent there, not because of their desire for freedom of thought and speech, but because they have been guilty of high treason or of actions directed against the community. It must also be said that no women and children are imprisoned in the concentration camps in order to bring pressure to bear upon their husbands and fathers.

It would be a good thing to keep political agitation and scientific research apart This is in the interests of science as well as in the interests of international scientific co-operation But when a scientist does mix politics with science, he should at any rate fulfil the first duty of a scientist, which is conscientiously to ascertain the facts before coming to a conclusion.

J. STARK.

Physikalisch-Technische Reichanstalt,
Berlin-Charlottenburg
Feb 2

WITH Prof. Stark's political Anti-Semitism I need not deal. to an unrepentant Englishman (without any Hebrew ancestry or Marxist allegiance) it appears absurd.

It is a fact, in spite of what he says, that many Jews, or part-Jews, have been dismissed from their posts in universities, although they served in the line in the German armies in the late War There are dozens of such in the lists of the Academic Assistance Council: whether they were "Beamte" or not is a quibble. Nor is there sense or justice in dismissing persons who were not "Beamte" before August 1, 1914.

Doubtless there are many grades of "dismissal", and in a technical sense certainly some of the persons in our lists were not "entlassen". They have found it impossible, nevertheless, to carry on their work in Germany. Men of high standing do not, without cause, beg their colleagues in foreign countries for help. Whether they were "dismissed", or "retired", or "given leave", or merely forbidden to take pupils or to enter libraries or laboratories is another quibble · the result is the same. It is inconsistent with that "freedom of scientific teaching and research" which the German Government apparently is seeking to restore.

As regards "high treason" and concentration camps, in England we do not call liberalism or even socialism by that name. The statement about women and children is a 'red herring'—I never said or suggested anything of the kind.

No doubt in Germany, after this reply, my works in the *Journal of Physiology* and elsewhere will be burned

May I take this opportunity of saying that the Academic Assistance Council (Burlington House, W 1) urgently needs funds—for in spite of all the quibbles, scholars and scientists are still being dismissed

Cytochrome and the Supposed Direct Spectroscopic Observation of Oxidase

IT has been shown previously[1] that some of the bands of the absorption spectrum, described by Warburg and his co-workers[2,3], in *Acetobacter* (*Bacterium pasteurianum*) and ascribed by them to the oxidase or oxygen transporting enzyme, do not belong to this enzyme but to cytochrome. It was also shown that similar absorption bands are visible not only in organisms with a very active oxidation, such as *Acetobacter* or *Azotobacter*, but also in organisms having a much lower respiratory activity, such as brewers' yeast, *Bacillus proteus*, *B. coli*, and *B. dysenteriæ*.

The study of micro-organisms reveals certain variations in the structure and properties of cytochrome. While in the majority of cases the absorption spectrum of cytochrome is similar to that found in bakers' yeast (1, Fig. 1) in other cases (2–6, Fig 1) the bands *b* and *c* may be replaced by one band (b_1), or band *a*, usually lying at about 603mμ, may be shifted either towards the short wave end (a_1, 586 mμ or 590 mμ) or towards the long wave end (a_2, 628 mμ or 630 mμ) of the spectrum

In *B. proteus* and *B. coli*, in addition to bands b_1, at 560 mμ and d_1 at 530 mμ, a very faint shading a_1 can be perceived at about 590 mμ and a band a_2 is clearly visible at 628 mμ. (This position having been determined with the reversion spectroscope is more correct than 630 mμ given previously.) On shaking the suspensions of these bacteria with air, the bands b_1 and d_1, are replaced by two very faint and diffuse bands at about 566 mμ and 535 mμ, while the band a_2, as was previously shown in *Azotobacter*[1], is replaced by a narrow band at 645 mμ (9, Fig. 1) which in the absence of oxygen, or on reduction with sodium hydrosulphite, moves back to 628 mμ.

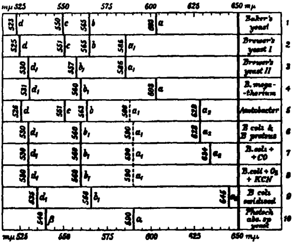

FIG 1 1–9, positions of the absorption bands of cytochrome in cells of different organisms Dotted line marks the faint shadings 10, position of α- and β-bands of the photochemical absorption spectrum in yeast and *Azotobacter* according to Warburg and his co-workers.

The bands at 628 mμ and 645 mμ represent, therefore, the α-bands of the reduced and oxidised component a_2. On shaking the suspensions of these bacteria with air in presence of potassium cyanide (8, Fig. 1) the component b_1 remains in the reduced form, while the band at 645 mμ disappears completely, as was recently shown to be the case in *Azotobacter*[4], or is more probably replaced by a diffuse band in the green, too feeble to be detected in the thick suspension of bacteria. The effect of potassium cyanide on the absorption spectra of these bacteria differs therefore markedly from its effect on *B pasteurianum*. In the latter, according to Warburg and his coworkers, potassium cyanide in presence of oxygen is responsible for the appearance of a band at 639 mμ

When the suspensions of these bacteria (*B. coli*, *B. proteus* and *Azotobacter*) are saturated with carbon monoxide, no change can be noticed in the yellow region of the spectrum (at about 590–593 mμ) where, under similar conditions, a narrow band appears in *B. pasteurianum*[2,3]. The band in the red (a_2), on the other hand, in presence of carbon monoxide is shifted from 628 mμ to 634 mμ (7, Fig 1) The carbon monoxide compound of the component a_2 has therefore its α-band (634 mμ) at least 400 A. nearer the red end of the spectrum than the α-band of the photochemical absorption spectrum (590 mμ) obtained with yeast or with *B. pasteurianum* and ascribed to the oxygen transporting enzyme

That the band in the red (a_2) does not belong to this enzyme is shown by its peculiar distribution in cells of various organisms. While this band is visible in a 4 mm. layer of a 50 per cent suspension of *B. coli*, it is invisible in a cake 8 mm. thick of bakers' yeast, the respiratory activity of which is, if anything, higher than that of *B. coli*. Moreover, in a mixture of a suspension of *B coli* with that of bakers' yeast, both bands *a* (of yeast) and a_2 (of *B coli*) can be seen simultaneously, which shows that the band a_2, if present, would not be masked by the band *a*. It should be noted, however, that the bands a_1 (586 mμ or 590 mμ) and a_2 (628 mμ or 630 mμ) have been seen so far only in cells where the typical band *a* (603 mμ) was missing

The components of cytochrome, as was shown previously, are hæmochromogen compounds which differ from artificial compounds like pyridine-hæmochromogen in that they do not usually react directly with molecular oxygen or carbon monoxide. These differences are, however, not constant. In fact, the components of cytochrome, being more or less labile, are easily modified under the influence of various factors and acquire the properties of artificial hæmochromogens in reacting with molecular oxygen and carbon monoxide

Of all the components of cytochrome, the component *a* is perhaps the most labile It is not surprising, therefore, that some of its derivatives such as a_1 in *B pasteurianum* or a_2 in *B coli*, *B. proteus* and *Azotobacter*, exhibit the above mentioned properties of the artificial hæmochromogen compounds

It may be stated in conclusion that all the absorption bands of hæmatin compounds seen by the direct spectroscopic examination of cells of different organisms belong either to free hæmatin or to the different components of cytochrome, and that no band seen so far can be ascribed to the oxidase or the oxygen transporting enzyme

Chemical Separation of the Isotopes of Hydrogen

IN their note on this subject[1] Messrs A. and L Farkas have reported the following values for the ratio, α, of the specific rates (H^1 H^2) at which the isotopes are discharged when the metals indicated undergo solution in water · Na, 1 2; Ca, 1 5, Al, 2; Zn, 4 Excepting the statement that sulphuric acid (0 1 *N*) was present during the dissolution of zinc, no indication is given concerning the conditions under which these experiments were performed

Similar experiments have been in progress here, which will be fully described in a paper shortly to be submitted to the Chemical Society, and the purpose of this note is merely to suggest that the figures recorded by Messrs. A and L Farkas are not to be regarded as characteristic constants of the metals. It would seem from a comparison of their results with ours that the value of α for any given metal must depend in some unknown way on the experimental conditions. For example, instead of 1·2 for sodium, we find 2·9, and this figure appears insensitive to the variations of conditions we have tried (2·8, 2·8, 3·0, 2·9 for media ranging from strongly alkaline to strongly acidic). Our ratios for calcium, 1·3–1·6, and aluminium, 4·0–4·9, seem to show a more definite dependence on conditions, the higher value in each case relating to reaction in an alkaline medium. The case of zinc requires special comment because pure zinc is scarcely soluble in dilute sulphuric acid, and, when impure zinc dissolves, the hydrogen is probably liberated at least partly at the impurities. The most nearly pure zinc we could get to dissolve, containing only a minute trace of carbon, gave the value 5·6, but commercial zinc gave a higher value, 6·8, and zinc-copper couples, prepared from pure (insoluble) zinc and varying quantities of deposited copper, yielded values ranging to 8·0. It seems possible that the use of metallic couples may prove a useful auxiliary method of concentrating the heavier isotope of hydrogen.

Our isotopic analyses have in all cases been carried out by determinations of the density of water, and in this connexion we would acknowledge the receipt of valuable help from Mr. J N E Day. We should mention that our experiments include the study of a number of other metals and also of some compounds which, on reaction with water, give volatile hydrides.

Electrolytic Concentration of the Heavy Hydrogen Isotope

Messrs R P Bell and J. H Wolfendon[1] have recently given their experience in concentrating the hydrogen isotope, namely, that nickel, platinum and copper are about equally efficient as cathodes, and in general the efficiency is surprisingly insensitive to the conditions of electrolysis. Broadly speaking, this is also the conclusion we have reached in a study of the electrolytic separation. There are, however, real differences between different metallic cathodes.

It is a convenience to have a name for the quantity α defined by $d \log H = \alpha\, d \log D$, and we propose the term "electrolytic separation coefficient" (this α is the inverse of the one used by Bell and Wolfenden).

The electrolytic separation coefficients of the metals which we have examined all lie between 7·9 and 2·8, the series in descending order being

Smooth Pt, Pb, Fe, Cu, Ag, Ni, W, Pt black, Ga liquid, Hg.

The coefficient is slightly lower in acid than in alkaline solution. In agreement with Bell and Wolfenden, moderate changes in current density do not make much difference. The position of lead relative to platinum and to mercury is remarkable.

With regard to the application of the over-voltage theory of Gurney, we should like to refer to one point. The theory in its original form implied that the atoms of H (or D) formed by neutralisation of the H_3O^+ (or H_2DO^+) ions are at a very high energy level, namely, the energy of free atoms further increased by the large positive potential energy possessed by the group H_3O at the moment of neutralisation. This involves a very high activation energy, and calculation shows that even if the whole of the applied over-voltage is drawn upon to reduce the activation required, no reasonable amount of current would pass from the solution to the cathode. It must, therefore, be supposed that the activation energy (known to be of the order of 10,000 calories from Bowden's measurements) is not so high as corresponds to the production of free atoms, because of the forces acting between hydrogen atoms and the metal atoms of the cathode surface. These forces modify both the potential energy curves $H^+—H_2O$ and $H—H_2O$, and since the isotopic separation depends on the steepness of these curves, different metals would give different electrolytic separation coefficients. But it seems to us that serious difficulties lie in the way of accepting the over-voltage mechanism proposed by Gurney, which we discuss in a forthcoming article.

Nature of Antibodies

It was found by Breinl and Haurowitz[1] that when proteins of an agglutinating serum had been coupled with diazotised atoxyl (*p*-amino-benzene-arsinic acid), the agglutinating power of the serum was not wholly lost. In this process, the proteins are themselves converted into azo-dyes, but the products are not strongly coloured. If, however, benzidine is tetrazotised, and coupled to *R* salt and to the serum proteins, according to the method of Heidelberger, Kendall and Soo Hoo[2], a deep red compound is formed, and the agglutinin again is not wholly destroyed.

If the agglutinins of the serum are proteins, this coloured product should be adsorbed specifically by homologous bacteria. Actually the protein dyes thus formed are readily adsorbed non-specifically. Nevertheless, if weak solutions are used, a striking quantitative difference can be shown between the degree of adsorption by homologous and heterologous bacteria. For example, two tubes (*A* and *B*) were put up. *A* contained a suspension of typhoid bacilli, eight minimal agglutinating doses of typhoid-agglutinin-dye (prepared from the euglobulin of typhoid agglutinating serum) and untreated cholera agglutinating serum. *B* contained a suspension of cholera vibrio in place of typhoid bacilli, the other constituents being the same as in *A*. After agglutination was complete, the agglutinated bacteria deposited in *A* were pink, while those in *B* were colourless. In the converse experiment, using cholera-agglutinin-dye, the cholera vibrios were coloured, the typhoid bacilli uncoloured.

This specific adsorption of the dye from the homologous coloured agglutinin is compatible with the theory that the agglutinins are proteins, but still leaves room for the alternatives: (1) that the agglutinin is attached to protein and not removed when the protein is coupled to the diazo compound, and (2) that the agglutinin is a non-protein aromatic substance which will form an azo-dye.

Supposing that the dye taken up specifically by the bacteria is protein-dye, the amount can be estimated colorimetrically. In example *A*, 1 ml of standard agglutinable suspension took up 2×10^{-6} gm; of the eight minimal agglutinating doses added, less than one dose was left in the supernatant fluid The minimal agglutinating amount for 1 ml of suspension is therefore about 2×10^{-7} gm, an amount less than that required to form a continuous layer on the surface of the bacteria. If this estimate is correct, it is not surprising that preparations of agglutinin should have been prepared in which protein could not be detected

Progestin in Placental Extract

SEVERAL facts have led to the supposition that the corpus luteum hormone, called progestin by Allen and Corner, should be present in the placenta; for example, the frequently observed continuance of pregnancy in women after removal of the two ovaries and the increased threshold for the action of œstrin in pregnant animals, even after castration (Courrier)

Collaborating with Dr. A. Luchs, two of us (P. d F and M. T) have tried in vain to extract progestin from the placenta and have published negative results[1] We had, however, obtained slight indications of activity of such preparations and therefore considered that the search for this hormone in the placenta should be continued. W. M Allen and R. K. Meyer[2] have recently described a method for the quantitative separation of progestin from œstrin and emphasised the importance of their method for the isolation of progestin from sources which are very rich in œstrin.

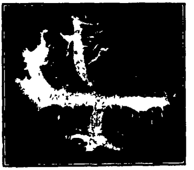

FIG 1 Proliferation of rabbit uterus after treatment with placental extract

Using their method, we have now demonstrated the presence of progestin in two lots of placenta. The first batch was extracted from full term human placenta and tested on an infantile rabbit (activated with œstrin after Clauberg's method) and gave distinct proliferation in a dose corresponding to 600 gm. of fresh tissue (Fig 1). The second batch was prepared from placenta of pregnant cows and tested on an adult castrated rabbit (6,800 gm) and on an infantile activated rabbit (500 gm) Both animals showed distinct proliferation of the endometrium in doses of 1,500 gm and 500 gm. respectively of fresh tissue The output of hormone is still rather low and our investigation is now being extended to a quantitative study of human and animal placenta obtained during pregnancy for other reasons than abortion.

Fine Structure of the *Kα* Line of Beryllium

THE *Kα* line of beryllium, occurring at the very long wave-length of 115 7 A, was measured by Söderman[1], who found it to consist of a broad band 10 A. wide In view of the recently discovered fine structure of the carbon *Kα* line, I have re-investigated the beryllium soft X-ray spectrum, and, as the spectrogram (Fig 1) shows, have found it to consist of two diffuse components That at the longer wave-length is the stronger The separation is 5 3 A or 4 8 electron-volts The measurement of the long-wave component is, however, difficult, as it coincides with the fifth order of oxygen *Kα* A comparison of the width of the component with that of the fourth order of oxygen *Kα* shows that it is too wide to be due to the oxygen line

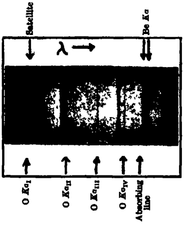

FIG 1

There are two possible explanations of the duplicity of Be *Kα* The first is suggested by the carbon *Kα* structure[2]. The carbon line consists of two (or possibly more) components The stronger of these is attributed to the C $K\alpha_{1,2}$ line and the weaker, short-wave component is probably the ordinary satellite $K\alpha_3$. A simple calculation of the expected separation agrees with the observed value. A similar calculation for beryllium also is in rough agreement with the separation given above The second possible explanation arises out of the fact that the surface of the beryllium is heavily oxidised in my experiments, and it is possible that, whilst one of the components obtained is due to oxidised beryllium, the other is due to the pure metal This possibility is now being investigated

Two other points of interest are observable in the spectrogram First, a faint absorption line appears at the short-wave edge of beryllium $K\alpha$ This absorption sets in at about 111 1 A Secondly, there is quite a strong satellite observable on the long-wave side of O $K\alpha$ at about 24 6 A More precise determinations of these wave-lengths will be published later.

Dynamics and Mechanism of Aliphatic Substitution

SLATOR[1] observed that alkyl halides and symmetrical ethylene di-halides react bimolecularly with sodium thiosulphate in water, but that the velocity of reaction with iodochlorethane and bromochlorethane was independent of the concentration of thiosulphate The phenomenon under discussion is the transition in kinetic order of a reaction due to a very slight modification in the structure of one of the reactants The problem has been discussed by E D. Hughes and Ingold[2], who reveal varied and more reliable instances of the same phenomenon For example, β-phenylethyltrimethylammonium hydroxide decomposes bimolecularly, whereas halides of the corresponding *p*-nitro derivative decompose unimolecularly

The velocity of hydrolysis of both ethyl chloride and tertiary butyl chloride depends on their concentration, but only in the former case is it influenced by the concentration of alkali The elimination of methyl alcohol and tertiary butyl alcohol from substituted sulphonium hydroxides are processes of the second and first order respectively (E D Hughes and Ingold[3]) According to the theory of Ingold, relating to reactions of type *B*, high cationic stability of the rejectable group and low nucleophilic activity of the reagent-anion tend to favour a unimolecular mechanism, which in turn admittedly implies a relatively long life to the activated organic ion

The question may now be raised whether the kinetic distinction observed between two similar but specific chemical reactions under ordinary conditions would persist at totally different concentrations In principle it is possible for the order of reactions of B_1 and B_2 respectively to become reversed below and above a critical concentration (*c*) of the reagent anion; *c* (in gram-molecules per litre) would be related to the *average* life-time (*t*) of the activated organic reactant (in seconds) by the equation

$$c = \frac{A}{t}\sqrt{\frac{\mu}{T}}$$

μ is the reduced mass of the molecules concerned; and *A*, which is a function of the molecular diameters, is approximately 11. From Slator's data, *t* for iodochlorethane becomes about 5×10^{-10} second. The Lindemann mechanism thus leads to plausible results when applied to reactions in solution; but it is noteworthy that change in kinetic order due to variations in the concentration, although sought[4], has not yet been found. This fact, and the demarcation between mechanisms B_1 and B_2 may have a common origin in the limited range of dilution conventionally employed.

There is no incompatibility between the two hypotheses. On the other hand, Lindemann's theory, accepted as the explanation of a well-known effect discovered by Hinshelwood in gaseous reactions, is in a sense complementary to Ingold's theory, which derives its support from the successful prediction of the course of organic elimination reactions.

Atmospheric Pressure and the Ionisation of the Kennelly-Heaviside Layer

EVIDENCE of a connexion between meteorological conditions in the troposphere, and the behaviour of radio waves reflected from the Kennelly-Heaviside layer has been noted by Colwell[1] in America and by Ranzi[2] in Italy. Again, Stagg[3] has discovered a relation between the diurnal variation of barometric pressure at Aberdeen and the general state of magnetic conditions over the earth There appears little doubt that some relation exists between conditions in the troposphere and the ionosphere

Evidence which appears to bear on the fundamental nature of the relationship has been obtained as a result of two series of experiments carried out in Melbourne and Sydney during 1931 and 1932

In the first series, carried out at the University of Melbourne with the collaboration of Mr R O. Cherry, during November–December 1931, and March–April 1932, the average night intensity of the sky wave from the transmitter 3 AR (610 kc /sec.) was measured at a distance of 90 km From the second series, carried out between Melbourne and Sydney on a frequency of 1415 kc /sec during October 1932, it was possible to find directly the maximum ionisation density in the *E* layer from observations of the rays of known angle which penetrated that layer.

From both series a very close direct correlation is evident between the average night-time ionisation density in the *E* layer and the barometric pressure at ground-level measured at a time ranging from 12 to 36 hours after the ionisation observation. For example, if on any night the average ionisation density is greater than that on the preceding night, then the barometer invariably rises within the time interval mentioned. In most cases the time lag is near to twelve hours, the greater lag being associated with slower moving disturbances

The results obtained in the first series of experiments are in complete accord with those of Colwell, though the explanation offered differs considerably from his Thus, Colwell considers that the "E layer is concentrated in the regions of low pressure"[4], resulting in a stronger post-sunset signal. On general theoretical grounds it is much more probable that a stronger night signal on the frequency of KDKA (980 kc./sec), upon which station Colwell's measurements were made, would result from a *decreased* intensity of ionisation in the absorbing portion of the

E layer. Such a deduction is even more probable for the frequency at which the first series of measurements described above was made, there being small possibility of electron limitation being operative so early in the night.

That this view is substantially correct appears to be shown by the remarkably close correlation found in the second series of experiments, which gave the ionisation density directly.

The relation of the results described above to those of Ranzi, which are principally concerned with the occurrence of abnormal night time increases in ionisation, is not so obvious. It seems clear, however, that in seeking an explanation of abnormal night ionisation, the possibility of horizontal movements of the ionosphere must not be overlooked. The phenomena described above strongly suggest the presence of winds at these high levels of the stratosphere.

This work is being carried out under the auspices of the Australian Radio Research Board, to which I am indebted for permission to publish this advance report.

Small Sand Craters of Seismic Origin

THE small sand craters of seismic origin, described by Dr. Sheppard in NATURE of December 30 (p 1006), as examples of unusual structures, are common results of severe earthquakes in alluvial regions. The formation of such vents and their related fissures was first explained by R. Mallet and T Oldham in the case of the Cachar earthquake of January 10, 1869[1], and their theory was adopted later by R D. Oldham in his description of the numerous and widely spread occurrences caused by the Great Indian earthquake of June 12, 1897[2]. Briefly, this theory postulates a certain amount of vertical movement from below, resulting in the transmission of the wave motion through layers of loose, oozy sand into the overlying, impervious and harder layers of the surface alluvium. The inertia of the latter is believed to cause a compression of the watery sub-stratum and the expulsion of part of its contents through simultaneously formed cracks above, usually as a geyser-like flow. The spurting which reliable eye-witnesses state takes place on these occasions, the return of the water when quiescence is attained and the formation of the craters with their scored sides, are all accounted for satisfactorily by this theory.

The epicentral tract beneath which the Pegu earthquake of May 5, 1930, originated, happened to form part of a vast alluvial plain in Lower Burma, and sand vents, craters and sloughs were produced over wide expanses of country as a result[3] Similarly, after the Pyu earthquakes of December 3 and 4, 1930, in Upper Burma, many examples were noted in suitable places, for their formation demands a bed of watery sand, overlain by a thick deposit of clay[4]. In no case, so far as they were examined either by my colleagues or myself, was any evidence found to lead to a modification of the older theory, still less to adopt the belief that they originated in a subsidence of the land, followed by a restoration to its original level, as stated by Sheppard. Insufficient attention has been paid in the past to the action of gas which may be so liberated from water-bearing strata charged with decomposing organic matter in such situations, but this would in any case only intensify the known, mechanical, surface effects of the disturbances.

The suggestion that the sandstone dykes of the Tertiary formations of south-western Ecuador may have been injected during earthquakes, recalls Kendall's identical explanation of the sandstone dykes and "fossil sand blows" of various parts of the British Coal Measures[5].

The Infinite and Eternal Energy

I SHALL be obliged if any reader of NATURE can give me the reference for Herbert Spencer's statement that:

"Amid the mysteries that become more mysterious the more we examine them, we find the one certainty that we are in the presence of an infinite and eternal energy from which all things proceed "

I quote from memory of reading this statement some forty years ago I think it was in the form of a letter on the completion of the "Synthetic Philosophy" I have failed to trace it at the British Museum or in Herbert Spencer's works, and the Herbert Spencer Trustees have been unable to find the reference for me. Prof. Wilhelm Ostwald had not heard of it, and he asked me for the reference; but I was unable to give it to him.

It was widely quoted and commented upon in the Press at the time it was published. Consequently, it is strange that there should be any difficulty in finding the reference

Tidal Bores

IN NATURE of February 3, p. 180, reference is made to a suggestion by Dr. Vaughan Cornish that a co-operative study of the Trent Bore should be undertaken by a group of students, equipped with tide-gauges, etc.

The late Mr. Champion devoted much time to observations in the Trent, using a special tide-gauge, at a large number of places. At his death we undertook to examine and collate all his material, which was presented to us by his sister. This work is nearly completed, and the results will shortly be published. The characteristic shape of the bore in detail, size, rates of travel, etc., have been deduced for a number of stations.

Research Items

Nudity in English Folk-Dancing. A photograph of a carved wooden panel, about 14 in. long, formerly in Lancaster Castle, representing figures apparently engaged in a morris dance, is published in the *Journal of the English Folk Dance and Song Society*, vol. 1, pt. 2, by Miss A. G. Gilchrist. The panel is of uncertain date, but is probably contemporary with Henry VII. There are seven figures represented, of which one wearing a cloak and feathered cap carries pipe and tabor, while another, wearing a high cap and distended skirt and bearing a ladle for contributions, is evidently the 'Maid Marian'. The fool wears cap and bells and carries a bauble or bladder The third figure in the processional is either a nude woman or a boy with artificial female characteristics personating a woman. Sir Edmund Chambers, to whom the photograph has been submitted, suggests a connexion with whatever it may be that lies at the bottom of the Lady Godiva legend and procession. There is evidence for the appearance of nude figures in English dances in the Puritan denunciation of "light, lewde and lascivious dancing" in which the "greatest abuse" of all was "dancing naked in nets", the morris dancers, it was said, coming to dance about church during divine service. It is to be noted that nude figures on misericords, dating from the fourteenth to early sixteenth centuries at Beverley St. Mary, Worcester, Norwich, and elsewhere, wear nets while riding on goats, stags or geese It has been suggested that these nets may have served the purpose of 'fleshings'. The subjects of medieval misericords seem frequently to have been derived by the artist from what he had seen in plays and pageants.

Growth Phases of the Organism of Cattle Pleuropneumonia. The micro-organism of this disease in some of its stages of growth is just on the limit of visibility and is filterable at times through a Berkefeld V filter. Bordet noted that in serum-broth cultures spirillar and filamentous forms develop together with small globular and ring forms. Other authors have suggested that some of these appearances may be artefacts, and various guesses have been made as to the position of the organism, which has been given such generic names as *Asterococcus*, *Micromyces*, *Mycoplasma* and *Asteromyces*. J C G. Ledingham has now studied the problem, and has obtained much information by the use of impression preparations of growth on solid media (*J. Path and Bact*, 37, No 3, 393; 1933) According to him, in the initial stage of growth, numerous deeply staining chromatic corpuscles are seen with ramifying filaments of varying length and containing in their substance small chromatic bodies. Detached pieces of filaments form the vibrionic forms of Bordet. The threads form complicated masses of filaments having much resemblance to actinomycotic colonies. Terminal and endomycelial chromatic nodes in the mycelial filaments swell up into large oval structures, and in the fully developed colony become surrounded with a thick sheath amidst the tangled mycelial threads. Ledingham considers that the organism, as well as that of 'agalactia' which was also studied, must be placed in the family *Actinomycetaceæ*. Filterability through filter candles, he suggests, may be due to an unusual plasticity of the protoplasmic structure.

Plum Rust Fungus on Apricot and Peach. The disease of the plum caused by a rust fungus, *Puccinia pruni-spinosa*, has been known to occur in English gardens for many years. A recent paper by Prof. E S. Salmon and Mr. W. M. Ware (*Gardeners' Chronicle*, Dec. 30, 1933, pp. 490–492) reports that the disease is now attacking apricots and peaches in several districts. The new hosts do not appear to be attacked very severely, and the damage caused is very slight in comparison with the heavy losses of American and New Zealand growers. Descriptions of the fungus are given in the paper referred to, and the interesting suggestion is made that the physiological variation described by Jacky as "form 2" has been introduced to Great Britain from the Continent. *Anemone coronaria*, the St. Brigid anemone, is the winter host of the fungus

Stocks for Cherries and Pears. The fundamental work of the staff of the East Malling Research Station on the standardisation of apple stocks is now being extended to the cherry and pear crops. In the *Journal of Pomology and Horticultural Science*, 2, No. 4, December 1933, two papers are published—"Stocks for Morello Cherries" by Mr. N H. Grubb (pp 276–304), and " 'Free' or Seedling Rootstocks in use for Pears; their Description, Selection, Vegetative Propagation and Preliminary Testing" by Mr. R. G. Hatton (pp 305–334) Three main types of cherry stocks were tried—sweet cherry, Mahaleb and acid cherry—and each type was budded or grafted with scions of Morello. Sweet cherry carried a scion growth of moderate vigour, but selected stocks showed considerable differences. Mahaleb was considerably larger than sweet cherry in the early stages, but later became weaker and more spreading in habit Acid cherry stocks were found to be distinctly dwarfing. Mr. Hatton has classified the free pear rootstocks of Europe, obtaining four main botanical groups (*A*, *B*, *C* and *D*) Some very striking differences in vigour of vegetative clones have been found, and tested under field conditions. The botanical groups all varied considerably, and it is interesting to note that the extremes of vigour were exhibited by members of type *C*. The stock numbered *C*7 produced a total wood-growth of 124 metres, whilst *C*4 only gave 58 metres.

Kerguelen Archipelago. Sir Douglas Mawson contributes to the *Geographical Journal* of January a paper on Kerguelen which embodies the results of his observations during the *Discovery* visit in the summer of 1929–30. The Kerguelen Archipelago, Heard and Macdonald Islands are considered to be subaerial features of a vast submarine rise on the floor of the Southern Ocean. This rise, which was traced by the *Discovery* into a high southern latitude, was formerly supposed to represent the remains of a submerged continental land mass, but Sir Douglas Mawson believes that the petrological evidence points rather to the Kerguelen area being an igneous blister on a deep ocean floor. It may, however, have been of considerably greater extent during the low-level stage of the sea in the peak period of Pleistocene glaciation. Another point of interest is the evidence that the present land topography owes most of its features to the work of ice. Sheet ice has done much of the work while deeply-cut glacial grooves are superimposed on the earlier more general erosion. It is clear that in places, particularly on the west, shelf ice did much to protect the coast from marine erosion. The paper includes a revised map of south-east Kerguelen.

Primary Standard of Light. In an article published in *World Power* of August 1933, Dr. J. W. T. Walsh gave a history of the attempts that have been made to establish a primary standard of light leading up to the work of Ives on the black-body standard. As a direct consequence of this work, the International Commission on Illumination recommended that the brightness of a black body under precisely defined conditions should be adopted as the primary standard of light. Following on these lines, the United States Bureau of Standards developed a form of black body standard which is regarded as very satisfactory. It consists of a small tube of refractory material held at the freezing point of platinum by immersion in a bath of the solidifying metal. The tube is made of thoria and the lower end is filled with powdered thoria. The apparatus is placed in an induction furnace operated by current at a million frequency. The brightness of the hole at the top of the tube is then measured photometrically. In a second article published in the January number of *World Power*, Dr. Walsh gives the results obtained with this apparatus at the national laboratories of France, Great Britain and the United States. These results are: France 58·84 international candles per square centimetre, Great Britain 59·10 and the United States 58·84. This shows that the standard developed at the Bureau of Standards represents a primary standard of light which is reproducible from specification to the precision of about a quarter of one per cent. This is a great advance on any previous proposal. The adoption of this standard will in no way affect the value of the international candle. Its only function is to ensure that there is no drift in its value.

Heats of Dilution. A study of the heats of dilution of aqueous solutions of zinc, cadmium and copper sulphates at 25° (Lange, Monheim and Robinson, *J. Amer. Chem. Soc.*, December 1933) has given results of interest in the theory of strong electrolytes. Within the limits of error, the measured (intermediate) heats of dilution were proportional to the square root of the molality below 0·001 molal. Although this is in agreement with the limiting Debye-Hückel law, the value of the factor of proportionality was not in agreement. The extension of the theory by Gronwall, La Mer and Sandved requires that the heats of dilution should fuse into the limiting law straight lines at very low concentrations. It was found, however, that the individuality of slope persists to the lowest measured concentration, 0·00005 molal, although this behaviour is not disclosed by other methods of measurement, such as electromotive forces and freezing points, a result which the authors suggest is partly due to the lower accuracy of such types of measurement. The values for the heats of dilution are also not in agreement with those found by the electrochemical method, although there is no theoretical ground for expecting the two methods to yield different results. The values for the *a* parameter (correction for ionic radius) in the extended theory are found to be different for zinc and cadmium sulphates, although the electrical method had given practically the same values, and the values of the initial slopes for these 2-2-valent salts were in poor agreement with the value required by the limiting law.

Cracking of Cement. A report issued by the Department of Scientific and Industrial Research (Building Research Tech. Paper No. 15, "Temperature Rise in Hydrating Concrete". London: H.M. Stationery Office, *1s 3d.* net) deals with the rise in temperature in concrete in the process of setting and hardening caused by the chemical reactions between water and cement. In large masses of concrete the rises in temperature may be considerable, and this may not only affect the properties of the material itself but also may influence the distribution and intensity of stresses throughout the mass. The fundamental cause of some of the serious cracking that has occurred in large masses of concrete, is the expansion due to the heat evolved during the hydration process followed by contraction during the subsequent cooling. Rapid-hardening cements attain a high strength during the period when the temperature is highest. During subsequent cooling the concrete may become subjected to internal strain, and this possibility has caused considerable concern among engineers. The report contains particulars of observations of temperature rises made on some fifty important concrete structures in various parts of the world. They show generally that with modern cements there is a tendency to attain higher maximum temperatures, and to attain these temperatures in a much shorter time, than was the case with cements formerly used. The report describes the laboratory methods developed at the Building Research Station for measuring the rise in temperature of a particular concrete under conditions simulating those of practice.

Design of Beam Arrays. One advantage of short-wave transmission in radio communication is that it is possible to concentrate the radiation to a certain extent in one direction, thus forming a beam of waves. In his classical experiments, Hertz showed that by using a parabolic reflector and placing the transmitter along the focal line, much more powerful effects were produced in a receiver placed on the focal line of a similar reflector when the reflectors faced one another. Hence these waves can be reflected by conductors. A series of vertical aerials with their bases on a parabola (called a beam array) will act like Hertz's reflector. In practice, great care is taken to ensure that the axis of the beam lies in a great circle path joining the transmitting and receiving stations, but hitherto little attention has been paid to the correct angle of elevation of the beam. In a paper read to the Institution of Electrical Engineers on January 3 by T. Walmsley, the results of an investigation into the factors controlling the economic design of beam arrays are given and definite conclusions are obtained. The author states that before the design of an array system is undertaken, tests should be made over several months to find the best angle of propagation in the vertical plane. If, as in the case of the Berlin-Rugby circuit, this varies appreciably with the season of the year, an array capable of having its angle of projection varied should be built. In the case of the Rugby-New York circuit, the best angle of projection—about 79° to the vertical—varies very little during the year. As the wavelength increases the cost of array systems for a given efficiency rapidly increases. In this case also the cost increases as the angle to the vertical at which the radio energy is required to be projected or received increases.

The Teaching of History and Prehistory in Germany

THE German Minister of the Interior, Dr. Frick, has issued a circular (under official reference number III 3120/22 6)[*] containing "guiding ideas" (*Leitgedanken*) for historical instruction in all German schools, and has transmitted them to all educational authorities in Germany. These "directive principles" (*Richtlinien*) have been issued also to the Union of School-book Publishers, and are to serve as a standard for the educational authorities in forming their opinion of historical textbooks submitted to them for adoption. Until the publication of these historical textbooks, which can scarcely be expected before Easter 1935, these "directive principles" are also to be regarded as guiding ideas for historical instruction in all German schools. We print below a translation, with German words and phrases in parentheses where there may be doubt as to the actual shade of meaning, of the full text of the document.

The directive principles are not intended, and cannot attempt, to give even by implication a survey of the whole material or the manner of its presentation. They rather direct attention to certain important points of view that hitherto have been considered inadequately, if at all, and that must accordingly be given greater prominence (*stärker zur Geltung kommen*) in future.

Prehistory should be mentioned first, since it not only locates the starting point of our continent's historical development in the Central European cradle of our nation (*Volk*), but is further, as a "pre-eminently national science" (*hervorragend nationale Wissenschaft*) (Kossinna)[†], better fitted than any other discipline to counteract the traditional undervaluation of the cultural level (*Kulturhohe*) of our Germanic (*germanischen*)[‡] forefathers.

Then from prehistoric times through all subsequent millennia until the present day, the significance of race must receive due attention; for it represents the ground (*Urboden*) from which all fundamental characters both of individuals and of peoples spring

A further point of view is the idea of nationality (*der völkische Gedanke*) as opposed to the international idea, the creeping poison of which has for the last hundred years been threatening to corrode the German soul itself; for Germans are more prone than any other people to pursue dreams that are not of this world

With the idea of nationality (*dem volkischen*) is intimately connected that of national citizenship (*der volksburgerliche Gedanke*). To-day a full third of all Germans live outside the frontiers of the Reich. Historical study in treating of German history must therefore not be restricted to the area comprised within Germany's frontiers, but must always keep in view the fortunes of our brethren (*Stammesbruder*) dwelling beyond them.

In opposition to tendencies of a different trend, it is to be required that the description of conditions of life (*des Zuständlichen*)—cultural history (*Kulturgeschichte*)—however important it may be for the characterisation of great periods of development, shall not be given pre-eminence over the political history which shapes the fate of nations. This means bringing out the forces that make history, so that the pupil shall not be lost in the bewildering multitude of isolated events, but shall grasp the main lines and deeper connexions and so be assisted in the formation of his political judgment and will (*und so in seiner politischen Urteils- und Willensbildung gefördert wird*).

The heroic idea in its Germanic expression (*der heldische Gedanke in seiner germanischen Ausprägung*), associated with the idea of leadership (*Führergedanke*) of our own day, that is linked with the earliest models of the Germanic past (*der an ältesten Vorbilder deutscher Vergangenheit anknupft*), must penetrate historical instruction at all stages The two together with their inherent heart-stirring power arouse the enthusiasm without which the study of history may easily become for the majority of pupils a tedious accumulation of facts (*Wissenstoff*). The heroic idea, however, leads on directly to the heroic outlook (*Weltanschauung*) which specifically befits us (*die uns artgemass ist*) as a Germanic people, as no other does, and inspires us with ever-renewed vigour in the struggle for national self-assertion (*völkische Selbstbehauptung*) in the midst of a hostile world.

In detail, the following points are still to be noted. The textbooks are to begin with an account of the primeval history (*Urgeschichte*)[§] of Central Europe (the Ice Age) and show how distinct races (Neanderthal, Aurignac, Cro-Magnon) were the bearers of specific (*arteigener*) cultures It can be shown, in primeval history already, that culture is a creation of race. This fact is only obscured, but not cancelled, by the racial mixtures of later times.

From the beginnings of prehistory (*Vorgeschichte*)[§] (post-glacial times) the Nordic and Faelic races spread over North and Central Europe. The principal areas of their distribution, as well as those of the remaining primary races of Europe, are to be illustrated with simple sketches. The history of Europe is the work of peoples of Nordic race (*nordrassischer Völker*); their cultural level (*Kulturhöhe*) is revealed to us not only by the relics they have left in the way of stone and bronze implements, but also by their achievements in the spiritual domain, that science can infer—not least in the highly developed Nordic (Indo-Germanic) parent tongue which has ousted (save for survivals) the languages of the remaining European races.

We take the path to Hither Asia and North Africa with the first Nordic invasions which must have taken place already in the fifth millennium B.C. This is indicated by finds of Nordic skulls in the earliest Egyptian graves and by the early-attested blonde population of the coastal region of North Africa (cf. Lapouge, "L'Aryen, son rôle social", Paris, 1885). The racial origin of the Sumerians is still obscure, but their language permits of hundreds of comparisons with Indo-Germanic roots which could be most readily explained by the assumption of a former upper class of Nordic conquerors (*die Annahme einer ehemaligen nordischen Erobererschicht*). A decisive influence on the history (*Eine entscheidende Beeinflussung der Geschichte*) of Hither Asia was first exercised by the Indians, Medes, Persians and Hittites, originally of Nordic stock (*nordrassischen*). The pupils must live through, as if it were that of their own blood-relations, the fate of these peoples who eventually declined, overwhelmed by the forces of foreign blood (*unter der Ubermacht fremdrassigen Blutes*) after they had created high civilisations in India and Persia

---

[*] The German text is published also in the *Nachrichtenblatt für deutsche Vorzeit, herausgegeben von Martin Jahn*, (IX 6), pp 81-84, 1933.

[†] Gustav Kossinna was professor of prehistory at Berlin until his death in 1932, founder of the Gesellschaft für deutsche Vorgeschichte and the periodical, *Mannus*, and author of numerous books amongst which, "Die deutsche Vorgeschichte, eine hervorragend nationale Wissenschaft", had a very wide circulation

[‡] *Germanische* is here translated "Germanic" instead of "Teutonic"; *deutsche* remains "German"

[§] German archæologists divide what in England is generally called "prehistory" into *Urgeschichte*—palæolithic times—*Vorgeschichte*—the Neolithic, Bronze and pre-Roman Iron Ages—and *Frühgeschichte*—the Imperial Roman and Dark Ages.

The history of the Greeks has again to begin from Central Europe. It must once more be insisted that it deals with our nearest racial brothers (*unsere nachsten rassischen Bruder*). Hence too our intimate relation to Greek art, quite different from our relation to Chinese, Japanese or Mexican art. The Nordic Greeks, as conquerors, formed the aristocracy (*Herrenschicht*) in the land. In Attica in the time of Pausanias, Carian was still spoken in the countryside by the indigenous population. Here in the south the struggle of classes (*der Kampf der Stände*) was based upon a contrast of races Both in Athens and in Sparta the full citizens constituted only a minority over against the indigenous population and the slaves; these, at least in Athens, were largely of Asiatic origin Hence with the breaking down of class barriers by the democracy and with the unrestrained mixture of races that followed, hastened by the growing decline in birthrate (*Kinderarmut*) (Polybios!) the fate of the Nordic race in Greece was sealed, and the decay of Greek culture proceeded with such furious speed that in barely 200 years the Greek people sank into complete insignificance. (Information on the racial aspect of this development in Günther, "Rassengeschichte des hellenischen und römischen Volkes".)

The history of the Nordic peoples of Italy must likewise begin in Central Europe, so that here too the racial kinship may be felt The struggle between patricians and plebeians is to be understood mainly (*vorwiegend*) as a racial struggle (*Rassenkampf*)—hence too the particularly fierce resistance to the grant of the right of intermarriage (*Ehegemeinschaft*) to the plebeians The Nordic element in the Romans was nearly worn out in unceasing wars. By the time of Tiberius only six of the old patrician families survived! The overwhelming majority of the total population of Italy consisted of the descendants of Oriental slaves. The hopelessness of their plight was the background for the stoic outlook (*Weltanschanung*) of the Romans. And so by the beginning of our era the denordicising (*Entnordnung*) of southern Europe was nearly complete

The significance of the Germanic folk-migration lies fundamentally in the fact that it brought fresh (*frisches*) Nordic blood into the Roman Empire, degenerated (*entarteten*) as it was through this racial hotch-potch (*Rassenmischmasch*). Hence the new culture of the Middle Ages bloomed (*entfaltet sich die neue Kulturblute*) only where Germanic peoples settled permanently in North (but not South) Italy, in Spain, France, England, but not in the Balkans. The racial influence of the Nordic Varangians (*die blutmassige Einfluss der nordischen Wardger*) in Russia was too slight to permeate the enormous region with civilising force Only the fact that the Germanic ruling class (*germanische Oberschicht*) in Central, West and South Europe was the bearer of medieval culture makes it possible to understand how medieval chivalry at its height exhibits everywhere such a uniform character

More emphasis than heretofore is to be laid upon the greatest achievement of the German Middle Ages, the recovery of the area east of the Elbe (*die Wiedergewinnung der ostelbischen Gebiete*) In this connexion, it must again be insisted with reference to conditions before the migration period that this area east of the Elbe right away to beyond the Vistula was once Germanic national soil (*einst germanischer Volksboden*) at a time when the Slavonic peoples still dwelt as poor fishermen in the Pripet swamps

For the rest, however, the insistence on nationality must not lead to an unfair estimate of the Middle Ages They were a time of very great expansion of German power (*grösster deutscher Machtentfaltung*). The foundation of national States was then achieved in no European country; take, for example, France with its constituent states (*Unterstaaten*)—Provence, Burgundy, Normandy, Ile-de-France and Lorraine.

Modern history reveals for the first time evolution in the direction of the national State Yet from the beginning of the modern period, international influences too make themselves gradually more strongly felt. They lead to a lamentable intrusion of alien elements (*zu einer beklagenswerten Uberfremdung*) into German blood, German speech, German law, German constitutional theory (*Staatsauffassung*) and finally into the whole outlook on the world. In opposition to them the development of German national consciousness is to be brought out; to-day it receives new vigour from the more thorough investigation of our own history (*des heimischen Altertums*). Such contemplation of what is specifically ours (*das Arteigene*) leads to greater emphasis on the bond of blood which unites us to our kinsmen in neighbouring regions and elsewhere abroad. It allows us to hope for increasing recognition in the kindred Germanic countries (*in den stammverwandten germanischen Ländern*), that the Nordic peoples must feel themselves a community united by destiny (*eine Schicksalsgemeinschaft*) upon the maintenance of which absolutely depends the existence of all higher Nordic civilisation.

The last twenty years of our own time must form a principal object of historical study. The terrific experience of the world war with the heroic struggle of the German nation against a world of foes, the disorganisation of our powers of resistance by forces hostile to the Fatherland (*vaterlandsfeindliche Krafte*), the degradation of our nation by the dictate of Versailles and the consequent collapse of the liberal-Marxist philosophy are to be treated as thoroughly as the incipient awakening of the nation, from the Ruhr struggle to the dawn (*Durchbruch*) of the national-socialist idea of freedom, and the restoration of the German national community on the Day of Potsdam

Minister Dr. Frick at the Ministerial Conference of May 9, 1933.

British Industries Fair

THE twentieth British Industries Fair which opened on February 19 is the largest national trade fair in the world. It is a visible and tangible epitome of the range, variety and character of the goods manufactured or produced within the British Empire, since only such goods are permitted to be displayed and no exhibitor may show articles other than those of his own manufacture The three principal sections of the Fair, held at Olympia and the White City in London, and Castle Bromwich, Birmingham, respectively, will remain open until March 2 To trade buyers the Fair is open from 9.30 a m until 7.30 p m. daily, the public are admitted daily from 4.30 p.m until 7.30 p.m , and on February 24 and March 2 they will be admitted throughout the day.

At Olympia the lighter industries are represented, while the furniture and textile industries have their displays at the White City The Birmingham (Castle Bromwich) Section is devoted to the 'heavy' industries such as hardware, sanitary ware, gas plant for industrial and domestic use, building, electricity, engineering, metals, mining and railway equipment.

It would obviously be impossible in a short article to review the exhibits, so as to give anything approaching a representative picture of the character of the Fair All that can be attempted is to direct attention to a few selected points likely to interest scientific readers

One interesting feature to be noticed each year at the Fair is the extent to which new scientific ideas, discoveries and inventions are being applied industrially. Sir Josiah Stamp and other writers have directed attention to the 'lag' between the completion of an invention or discovery, on the laboratory scale, and its routine incorporation, in applied form, in large-scale industrial operations. The annual exhibition of the Physical Society always has some feature or features of novel scientific interest . how long is it before such a new scientific idea becomes routine practice in the workshop ? One may get some indication of the lag by noticing how long it is before the same idea is embodied in some industrial product exhibited at the British Industries Fair.

In the hardware, ironmongery and brass-foundry group of exhibits at Castle Bromwich, the number of chromium-plated products shown indicates how greatly the improved technique of the electrochemical deposition of chromium is being applied industrially—repeating, it may perhaps be said, in this connexion the older story of stainless steel At Birmingham the latest scientific improvements in equipment for general heating and cooking, and in furnaces for the metallurgical industries are exemplified in numerous exhibits. In the exhibition of electrical plant and accessories there are new and interesting features in generators, motors, transformers, rectifiers, condensers, accumulators and switchgear Recent developments in electrification have called for high-speed rotary machines ; and the comparatively new industry—that of plastic moulding —has had its repercussions on the engineering industry by giving an impetus to the production of special presses. Similarly, the demands of motor and aircraft engineering have led to the evolution of acid-resisting and rustless steels and of new light-weight alloys having great tensile strength. All these and many other developments may be seen in the exhibits at Castle Bromwich.

At Olympia an exhibit of special scientific interest is the United Scientific Instrument Exhibit Among the cinematograph machines shown, both for taking and for projecting, there is a pocket cinematograph camera which, by the turn of a switch, can be converted into a cinematograph projector. It is shown by Camera-Projectors, Ltd. At the stand of Messrs. Chance Brothers and Co , samples and mouldings of a selection of optical glasses representing more than one hundred varieties made by the firm are shown. Messrs. Cooke, Troughton and Simms, Ltd., of York, appear in a new rôle, as manufacturers of a complete range of microscopes for biological, medical and metallurgical studies A gas-filled hot-cathode rectifying valve is shown by Messrs Partridge, Wilson and Co , of Leicester, for the conversion of alternating into direct current. Messrs. Ross, Ltd., exhibit, besides a wide range of their famous camera lenses, including lenses for cinematograph work, a complete portable cinematograph projector and an epidiascope.

A novel and interesting piece of apparatus—called the 'hydro-pulsator'—is shown by Mr Lee Guinness It provides a high-pressure jet of water pulsating at high frequency It is claimed that the apparatus provides a mode of vibratory massage suitable for application to the gums and other parts of the body too sensitive to be touched by the hand, and that by it the teeth may be more efficiently cleaned than by a tooth brush. Messrs. Ensign, Ltd , exhibit the "Ensign Midget", said to be "the most compact camera yet constructed" Besides a complete range of their well-known microscopes, Messrs R and J Beck, Ltd , show a series of workshop projectors by which operatives may see on a ground-glass screen the magnified images of engineering and other products, the profiles of screws and similar components.

The chemical industry is, of course, well represented and the exhibits form a most noteworthy feature of the Olympia Exhibition.

University and Educational Intelligence

BIRMINGHAM —In the annual report of the Vice-Chancellor it is announced that the number of full-time students has reached 1,840 (the maximum yet attained). The increase in the number of medical students is resulting in congestion which can only be relieved by the completion of the new Medical School adjoining the new Hospital Centre near the University Buildings. A beginning has been made with the Hospital Centre and the work is progressing rapidly, but the magnitude of the scheme is such that it is not expected that the first instalment (of 500 beds) together with the complete Medical School, will be ready before the autumn of 1937. An increase in the accommodation for the Department of Chemistry is also urgently needed, but as the estimated cost is £50,000, this cannot be undertaken until the expenditure required for the Medical School can be definitely ascertained. A chair of applied mathematics is also needed.

In the report the Vice-Chancellor refers to the problem of the quality of University students in general. He considers that of all classes there is not more than about 4 or 5 per cent of the first quality, and the university that can offer the most valuable entrance scholarships is likely to secure the greater proportion of these. On the other hand, there are about 20 per cent who, being much below the average of ability, only just manage to get degrees, and it is these who constitute the 'unemployment problem'

The claims of the Library are again urged: "If our ideal as a University is education and not merely the maintenance of intellectual disciplines, double the sum that we now spend on it would be sound and rewarding expenditure".

Dr. H. P Gilding, formerly reader in experimental physiology in University College, London, has been appointed professor of physiology in succession to Prof. I. de Burgh Daly, who has been appointed to the chair of physiology at Edinburgh.

LONDON.—The title of reader in the University has been conferred on the following in respect of posts held at the Colleges indicated: analytical chemistry, Dr. H. F. Harwood (Imperial College—Royal College of Science); pathology, Dr Joan M. Ross (London (R.F.H.) School of Medicine for Women); statistics, Dr. E. S. Pearson (University College).

OXFORD.—On February 13, Congregation passed the Statute, the preamble of which was approved on January 23, for extending and improving the provisions for the study of forestry in the University. The Statute passed without a division, but considerable opposition was offered to a decree providing a site for the proposed new forestry building in the area of the Parks allotted for the extension of scientific departments, in case a suitable site should not be found elsewhere. In proposing the decree, the Master of Balliol pointed out that the moment had arrived when a definite decision must be taken; the whole future of forestry at Oxford was at stake. If the decree were thrown out, co-operation with the Government would be imperilled. The decree was opposed by Prof R. A. Peters, who denied that the honour of the University was at stake The Colonial Office must have known that no commitment could be entered into without the consent of Congregation Further exploration should be undertaken of other possible sites. The Warden of New College urged that this was not a purely domestic matter, the India Office, the Colonial Office, all the Dominions and Crown Colonies were involved. Those who opposed the decree would run the risk of destroying the centre of higher forestry instruction for the whole Empire Prof F. A. Lindemann said that the proposed site was unsuitable and undesirable. The decree should not have been brought in until other sites had been explored. The general opinion of the heads of scientific departments, though they wished forestry well, was unfavourable to the proposed site. The danger of exceeding the alleged time limit had been exaggerated. On a division, the decree was carried by 122 to 91.

A SHORT Unity History School will be held at Bath on April 20–23, at which discussions in connexion with present risks to peace in the world, the effects of dictatorships on world peace, and the effect of science on world peace will be introduced by Prof. H. Dingle, Imperial College of Science and Technology, Prof. R. B. Mowat, University of Bristol, and Mr. F. S. Marvin. A more extended School will be held at Rome in 1935, when the subject will be "Science in the Modern World". Further information can be obtained from Mrs. K. E Innes, 29 High Oaks Road, Welwyn Garden City, Herts.

FOUR Lady Tata research scholarships, of the value of £400 a year each, will be open for award in June 1934, to men or women of any nationality, for research work in the subject of blood diseases, with special reference to leucæmias. Each will be tenable for a year, from October 1, 1934, and renewable up to a normal maximum tenure of three years Candidates for these scholarships must send their applications in time to be received in London on April 15, addressed to the Secretary, Dr H S Patel, Lady Tata Memorial Trust, Capel House, New Broad Street, London, E C 2, or Prof. A. Vacha, Calvinstrasse 27, Berlin, N.W 40, or The Lady Tata Memorial Trustees, Bombay House, 24, Bruce Street, Fort, Bombay, from whom forms of application may be obtained.

Science News a Century Ago

Death of Alois Senefelder

On February 26, 1834, Alois Senefelder, the inventor of the art of lithography, died at Munich at the age of sixty-two years The son of an actor, he was born at Prague on November 6, 1771, and after leaving school studied law at the University of Ingolstadt. His father died early, leaving him to support the family, so he turned to the stage, but with little success Something of a poet, a painter and a musician, he then began to write comedies, and it was through his efforts to produce copies of these that he was led to his invention. Etched copper plates proved too expensive, so he tried writing on a fine white limestone and removing the untouched surface with acid. By about 1797 he had adopted the method of drawing upon the stone with a greasy substance which had an affinity for printing ink. He was granted an exclusive privilege for the process in Bavaria in 1799, and he took out an English patent on June 20, 1801 The next few years were devoted to the development of the new art and in 1809 he was given the post of director of the royal lithographic office in Munich; this position he held with a good salary for the rest of his life. In 1818 he published his "Lehrbuch der Lithographie", in which he gave an account of his discovery, and this was translated in the following year into English by his fellow countryman, Rudolph Ackermann (1764–1834), who had a print-shop in the Strand, London Some of Senefelder's original apparatus is preserved in the Deutsches Museum, Munich.

Aurora Borealis

On February 26, 1834, the *Times*, under the above title, published the following extract from the *Westmoreland Gazette*: "This beautiful phenomenon is not often seen in this part of the world during the day, but at mid-day on Thursday we had something very like it. About 1 o'clock three stripes of pale light emanated from a cluster of fleecy clouds resting a few degrees above the horizon, and about a point to the eastward of north, shooting up beyond the zenith till it came in contact with other clouds, when they melted away; one stream was about mid-heaven, the other more eastward. About half-past one there shot from the same clouds the most beautiful stream of pale light one ever beheld—broad at the base, but extending in width as it shot upwards, not unlike a noble plume of feathers, its progress to the zenith was rapid, but as it passed this point it melted away in ether"

Faraday and Northmore

Faraday's care to give credit to others who had made scientific investigations is recalled by a letter written on February 27, 1834, by Octavian Blewitt (1810–1884), the author of a "Panorama of Torquay" to the editor of the *Philosophical Magazine* The letter corrected a statement made to Blewitt by Thomas Northmore (1766–1851), the Devonshire man of science who had complained that Davy, Faraday and other philosophers had failed to acknowledge his work on the condensation of gases, an account of which was published in *Nicholson's Journal* of 1805–6 When Blewitt brought this to the notice of Faraday, the latter referred to the *Quarterly Journal of Science* of 1823 in which he had said The most remarkable and direct experiments I have yet met with in the course of my search after such as were connected with the condensation of gases into liquids are a series made by Mr Northmore in the years 1805–6" This answer apparently satisfied Northmore who expressed regret that he had been ignorant of this reference

Royal Society, February 27, 1834

Capt de Roos's paper on the operations for raising stores lost in the wreck of H M S *Thetis* off Cape Frio, on the South American coast, was concluded A paper was read by George Dollond, giving an account of the application of a concave achromatic lens to the micrometer, proposed to be called the *macro micro* lens The author stated that by introducing one of the fluid concave lenses recently invented by Prof Barlow, between the object glass and the eye piece of a 5 ft telescope, it became as powerful as a 10 ft instrument The invention had been regarded as one of the greatest improvements made in optical instruments for many years This application of a concave achromatic lens arose out of the series of trials that were made for the purpose of correcting the aberrations of the eye glasses applied to the telescope constructed by the author for the Royal Society

Palestine Association

A general meeting of the Palestine Association, convened by advertisements in the public journals, was held on January 28, 1834, in the rooms of the Royal Geographical Society, Lower Regent Street, and Mr (afterwards Sir) Bartle Frere occupied the chair It was reported that no meeting of the Association had been held since April 24, 1805, and that no steps had been taken to continue the researches in Palestine since the year 1809 It appeared that there remained in the hands of Messrs Coutts a sum of £135 9*s* 8*d* belonging to the Association.

Following discussions in February, it was resolved that steps should be taken to transfer this sum to the Royal Geographical Society to form part of its general fund and to be employed as the council of that Society might think fit for the promotion of geographical discovery Also, that all papers, books, etc, belonging to the Palestine Association be transferred similarly (Minutes, Palestine Association).

Societies and Academies

London

Royal Society, February 15 J C Stimson The electrical condition of hot surfaces (5) The rates at which the steady equilibrium potentials are built up on gold, nickel, platinum, carbon, and copper surfaces after earthing have been studied under varying experimental conditions The rate of charging up of a surface is a linear function of its instantaneous potential, and its logarithm is directly proportional to the reciprocal of its absolute temperature It is extremely probable that the hot surfaces emit positive electricity over the temperature range investigated (up to 850° C) When heated in a vacuum, the emission probably consists of positively charged metal ions, while in contact with gases, the ions are positively charged atoms or molecules of the gas With oxygen at low temperatures however the ions appear to be negatively charged G I Finch and B W Bradford The electrical condition of hot surfaces (6) A series of experiments with a gold gauze surface was carried out in such a manner that the catalytic and electrical activities of the metal could be simultaneously observed and followed The reaction selected was the heterogeneous combination of carbon monoxide and oxygen in both moist and dry systems The electrical condition of the metallic surface was expressed in terms of the magnitude and sign of the equilibrium potential which it acquired in given conditions and its electrical activity was measured by the specific rate at which that potential was approached on insulation at zero or other standard potential In general, throughout the experiments changes in the rate of electrical charging of the metal followed closely the corresponding changes in the catalytic activity, increasing with rising temperature or with the introduction of water, and undergoing similar variations to the rate of reaction when the surface was maintained at constant temperature G I Finch and A W Ikin The catalytic properties and structure of metal films (2) The surface potentials and rates of charging up of cathodically sputtered platinum films in contact with electrolytic gas at room temperature have been determined, and the film structure examined by the method of electron diffraction It is concluded that (1) catalytic action is determined by a prior interaction between the surface and one or both constituents of the combining mixture, whereby the catalyst becomes electrically charged (2) activity is not determined by either crystal size or orientation, (3) catalytic activity appears to be centred round isolated atoms or molecules of platinum not forming part of any ordered array or structure S F Boys Optical rotatory power (1) A theoretical calculation for a molecule containing only isotropic refractive centres (2) The calculation of the rotatory power of a molecule containing four refractive radicals at the corners of an irregular tetrahedron A theoretical formula connecting rotatory power and chemical constitution has been obtained on the basis of the electronic theory of dispersion The rotatory power of any molecule is expressed in terms of the ordinary refractive properties and the linear dimensions by means of certain determinants The expression for the rotatory power is applied to the special case of the molecule containing four radicals attached to one atom, when it becomes quite simple, and theoretical predictions of rotations are compared with experimental data. The formula explains the variation of rotatory power with chemical substitution and also the effects of temperature and solvent The rotatory dispersion is expressed in terms of the refractive dispersions of the radicals in the molecule. The formula also connects the sense of the rotation with the absolute configuration of the compound, and this should be of vital importance in the study of Walden inversion reactions.

EDINBURGH

Royal Society, January 8. Mary G Calder. Notes on the Kidston collection of fossil plant slides (3). Some points in the anatomy of *Sigillaria elegans*, Brongniart. Certain important unrecorded features of the anatomy of *Sigillaria elegans* are described, the specimens on which the description is based having been identified from external characters (4): On the nature of the corona and its relationship *to the leaf traces in the Sigillariæ and Lepidodendreæ*, with special reference to certain diploxyloid specimens in the Kidston collection. In order to establish the affinities of certain diploxyloid specimens, to which the name of "Sigillaria lepidophloioides Kidston MS" had been given, the information regarding the nature of the corona and its relationship to the leaf traces in the Sigillariæ and Lepidodendreæ is reviewed. The specimens are finally referred to *Lepidodendron cf Harcourtii*, Witham David Waterston: New light upon Bishop James Kennedy (1400 ?-1465) from an examination of his remains, recently disclosed during alterations to the College Chapel at the University of St Andrews The skull is mesocephalic, but Alpine rather than Nordic. An endocranial cast shows a large and highly developed brain There had been a fracture of the clavicle which had been treated creditably, a cervical rib, extensive spondylitis of the spine and some occupational modifications. R Grant Studies on the physiology of reproduction in the ewe (3) Gross changes in the ovaries Œstrus is associated with growth and rupture of one or more follicles and interœstrum with the development of endocrinologically active corpora lutea Ovulation is spontaneous and occurs 18–24 hours after the beginning of œstrus Ovulation and formation of corpora lutea occur also during the last month of anœstrum Active corpora are present in pregnancy until about two weeks before parturition In lactation and most of anœstrum, the ovaries are quiescent.

Five fragments of jaws, apparently closely related to the tarsiid lemurs (*Anaptomorphidæ*) including the Eocene genera *Omomys*, *Hemiacodon* and *Euryacodon*, have been found at Sespe, north of the Simi Valley. Descriptions and photographs of the fragments are given. J. L. Walsh: Note on polynomial interpolation to analytic functions. Selig Hecht and George Wald: The influence of intensity on the visual functions of *Drosophila* For intensity measurement a series of plates bearing translucent bars of different densities were used; for visual acuity, plates with opaque bars of different widths. A single fly in a glass cell is observed when illuminated with varying intensities of light passing through such plates. At low illumination, two lights are discriminated when the ratio of intensities is nearly 100; this decreases with increased intensity (I) to 2·5. Visual acuity varies with log I, increasing in a sigmoid manner with increase of log I. Assuming the reciprocal of $\Delta I/I$ measures visual acuity, the ratios *Drosophila*/bee/man are 1/60/249 for maximum intensity discrimination, and 1/9 4/1110 for maximum visual acuity. The differences are related to the variation in number of elements functional in the retinal mosaic. T. D A. Cockerell and Louise M. Ireland. The relationships of *Scrapter*, a genus of African bees Cytological and morphological details of insects often suggest 'lateral evolution', that is, a type gives rise to new types without itself disappearing. Moreover, various genes appear to remain latent for long periods. As regards *Scrapter*, from Africa, and *Euryglossidia*, from Australia, though superficially closely alike, they seem not to have had a common ancestry with their special generic characters Oswald Veblen: Spinors in projective relativity. A formal development of the generalised Dirac equations. W A. Zisman: Corrections to earlier papers (see Nature, 132, 687, Oct 28, 1933). All values (statistical) of Poisson's ratio are 5 5 per cent too small. The general conclusions are unaffected

Forthcoming Events

[*Meetings marked with an asterisk are open to the public*]

Monday, February 26

Royal School of Mines, South Kensington, at 5 30—Prof J A S Ritson "Explosives and their Use in Breaking Gound" (succeeding lectures on February 27 and 28, and March 1) *

East London College, at 5 30—Prof G I Finch · "High Voltage Oscillographs" (succeeding lectures on March 6, 12 and 19) *

Royal Geographical Society, at 5 30—G. Rayner "Observations in the Southern Ocean" (Geographical Film)

Tuesday, February 27

Royal Society of Arts, at 4 30—Prof C G Seligman "Anthropological Research in the Southern Sudan".

University College, London, at 5 30—Prof. L. Ruzicka "The Many Membered Carbon Rings" (succeeding lecture on March 1).*

Thursday, March 1

Royal Society, at 4 30—C. Sykes and H Evans · "Some Peculiarities in the Physical Properties of Iron-Aluminium Alloys"

A J. Bradley and J. W. Rodgers: "The Crystal Structure of the Heusler Alloys".

Friday, March 2

Bedson Club, at 6.30.—Prof J. Kendall "Elements, Old and New" (Twenty-fifth Bedson Lecture).

Royal Institution, at 9.—Dr. H. J Gough: "Current Research Problems in Engineering".

Geologists' Association—Annual General Meeting A L. Leach "The Isle of Caldey its Geology and Archæology" (Presidential Address).

Saturday, March 3

Royal Institution, at 3—Lord Rutherford. "The Transmutation of Matter" (succeeding lectures on March 10, 17 and 24).

Management of Industrial Research

THE paper by Dr Friedrich Bergius delivered before the Institution of Chemical Engineers on November 15 last describing the development of the process of wood saccharification up to a commercial scale at Mannheim has a much wider interest than in relation to the actual manufacture of glucose, lignin or acetic acid It provides a striking example of the difficulties which are so frequently encountered in the transference of a process from a laboratory to an industrial scale, but it possibly provides an even more impressive example of the way in which the prosecution of industrial research in one direction reacts to the advantage of industry in many other ways

Dr Bergius laid particular stress on the large amount of experimental work required to find the right form of apparatus and the proper constructional materials In the course of these investigations, a knowledge was acquired of the properties of different kinds of special materials and combinations of materials to protect metal parts against hydrochloric acid, which should be of widespread utility in chemical engineering Apart from this, the successful conclusion of the investigations depended largely on the development of an adequate engineering technique as well as on the solution of the chemical problems involved, and problems arising out of the low conductivity of stoneware, for example, as well as out of corrosion difficulties, were also encountered It is interesting to note that after a satisfactory solution had been found by utilising the principle of direct transfer of heat from a fluid conductor to the solution to be distilled, the introduction of stoneware with a much higher heat conductivity avoided the difficulty by allowing the construction of suitable vacuum stills

The multilateral benefits of industrial research are, however, equally well illustrated in the address which Sir Kenneth Lee delivered before the Royal Institution on December 15, in which a review of the research work leading to the commercial development of creaseless cotton fabrics by Messrs Tootal Broadhurst Lee and Co., Ltd , was accompanied by shrewd and pertinent observations on the general principles of industrial research which are worthy of widespread attention

One of the first points stressed by Sir Kenneth in regard to the direction of industrial research was the selection of a definite objective, and he attributed the successful issue of the research campaign largely to the selection of a definite and appropriate subject It would be easy to multiply examples of success in industrial research which have similarly followed the selection of a target or objective which was worth while and was clearly defined. The manufacture of synthetic indigo, the fixation of atmospheric nitrogen, the hydrogenation of coal, the saccharification of wood, or the development of numerous synthetic chemicals from acetylene, for which the first award for chemical engineering to a company was made to the Carbide and Carbon Chemicals Corporation at the Fourteenth Exposition of Chemical Industries, New York in December—these are all examples of investigations in which the first step was the definition of an objective worthy of the expenditure of effort involved

Although such examples are so familiar, it is scarcely sufficiently realised that industrial research is largely a matter of selecting appropriate targets or objectives, and that such selection forms a large part of the science and art of research management Success in this field to-day is largely a matter of clearly visualising objectives which are worth while and bringing to bear on them a team of highly skilled research workers equipped with all the technical resources which the modern industrial research laboratory can place at their disposal.

When this has been said, however, it must be admitted that a considerable amount of accurate fundamental knowledge is essential if wise selection of research objectives is to be practised It is precisely the absence of a more or less accurate knowledge of the broad outlines of their field in which certain industries in Great Britain are deficient, and until they have built up such a general body of scientific knowledge covering the principles and practice of their industry, then the research they prosecute is unduly at the mercy of chance. Sir Kenneth Lee, for example, emphasised how the absence of previous systematic research in the cotton industry necessitated much fundamental research before any real progress could be made with the specific problem of producing a creaseless cotton fabric, and how the growth of such knowledge contributed to the clearer definition of the research objective

The selection of an appropriate objective and the existence of an adequate foundation of scientific knowledge are as important to successful industrial research as they are indeed to the successful conduct of industry, whether of an old established industry such as the textile industry or of the new industries such as rayon, dyes, radio, etc., which are firmly based on scientifically established facts Equally important, however, is the matter of team work Industrial research is rarely a matter for one class of research worker alone. Co-operation between chemist, engineer, physicist and others is almost always required, and freshness of outlook and capacity to conduct research are often more important than a prolonged technical experience, which may make for less receptiveness to new ideas Moreover, in the difficult intermediate stage between laboratory success and actual manufacture, the man with a good general training may be more useful than the brilliant but sometimes over-specialised research worker

It is this overlapping of various sciences in industry which makes the multilateral or incidental advantages of industrial research so important and also, apart from success or failure in the main objective, tends continually to raise the general standard of day-to-day practice in an industry which encourages research On this ground alone, Sir Kenneth Lee's assertion that the time is opportune for a considerable expansion in industrial research in Great Britain is thoroughly justified.

Relevant to this question is that of service, to which Sir Kenneth also alluded The selection of valuable objectives is largely dependent on an accurate and scientific knowledge of the principles and practice in the various industries in which the products of a particular industry are used As Sir Kenneth pointed out, the three main defects of goods sold by his company have all been overcome by research conducted either by themselves or by other industrial firms the fastness of the dyes has been greatly improved the creasing difficulty has been solved , and a solution has also been found to the shrinkage problem There are indeed few fields in which the advantages of industrial co-operation are more obvious than in the matter of continuously raising the standard of service given by the products of an industry

Despite the considerable volume of industrial research now being carried out in Great Britain, there are many signs which indicate that industry as a whole is far from making full use of research. Even such a rough pointer of research activity as the number of patents taken out in different countries indicates an alarming disparity in the number of patents taken out in Germany or the United States as compared with Great Britain by persons resident in those countries. Moreover, even the newer industries, which are based on scientific knowledge and are vigorously prosecuting research, are often paying heavy tribute to foreign countries in the form of licences to work fundamental processes covered by master patents. The number of industries in which the fundamental discoveries and master patents are of entirely British origin is disappointingly small.

It is true of course that the position is steadily improving in certain industries, such as the electric lamp industry and also in metallurgy, by the expiry of some of the master patents, but that improvement can only be temporary unless British industries, through a vigorous research policy, are able to claim a full and progressive share in the discoveries upon which further industrial developments are based. The subjects for research are almost legion. To select the major and most profitable problems for investigation is an embarrassing task and may well demand, as a first step, commercial research—the analysis of market probabilities and possibilities, the interplay of main products and by-products, the effect of displacing existing by new products—linked with scientific knowledge, wide vision and sound judgment, on a scale which is still by no means common in British industry.

This plea for research as an essential element in business policy is all the more opportune when the whole question of financing industrial research is under consideration. Whatever plans may be evolved by the Government for the endowment of industrial research and for stabilising that endowment, so as to eliminate the threat of day-to-day financial and economic exigencies whether in public funds or industrial prosperity, the need of vigorous internal prosecution of research by industry remains. This is not even a matter for international trade alone. It is equally important in the home market, where opportunities are largely dependent on the adoption of adequate development policies by unrelated industries.

We have come at last to the realisation that the condition of an industry is not solely a matter for that industry alone. A depressed industry depresses other industries, and if that industry is depressed primarily or even partly because of its own negligence of inefficiency, public interest now demands that appropriate measures be taken to remove that neglect of inefficiency. Sir Kenneth Lee's exposition of research and business policy is a valuable reminder of the factors which make for industrial success and prosperity. Dr. H. Levinstein recently asserted that much of the progress achieved by Japan in recent years is to be attributed to Imperial endowment of the Institute of Physical and Chemical Research. We have undoubtedly the necessary scientific ability to undertake all the industrial research required, whether of the fundamental or technical and semi-commercial kind. What must be brought to bear are the trained intelligence and restrained imagination which are adequate to plan the research required to make full use of all our available resources, and, while continuously raising the general standard of everyday industrial practice, to secure also such a share in the developments of industry as will enable us to meet foreign competitors on equal terms in regard to technical skill, industrial efficiency and freedom from patent restraints.

The Technique of Human Genetics

Nature and Nurture: being the William Withering Memorial Lectures on "The Methods of Clinical Genetics" delivered in the Faculty of Medicine of the University of Birmingham for the Year 1933. By Prof. Lancelot Hogben. Pp. 144. (London: Williams and Norgate, Ltd., 1933.) 6s. 6d. net.

IT is a significant fact that in recent years the editorial columns of NATURE have become more and more concerned with the relation of science to the State. These articles give expression to the conviction which has been growing among men of science that they have certain responsibilities to the community in which they live, and that they should no longer be diffident in offering to help in the solution of the social and economic problems which beset it, by the application of the scientific method in which they have been trained and the special knowledge which they possess. The book under review, which is written by the professor of social biology in the University of London, is a summary of recent work on one phase of the application of science to human affairs, and is therefore of more than purely parochial scientific interest; at the same time the scientific community will be glad to see such problems are being treated with the earnestness, daring and caution which are characteristic of the scientific spirit.

The particular aspect of human biology in which Prof. Hogben has interested himself is heredity. The genetical study of plants and of animals other than man is already in an advanced stage: genetics is in a position to give a causal account of its data which is as complete and coherent as any which can be offered in other branches of biological inquiry Its practical triumphs, the creation of new species in plants, and of new animal varieties adapted to particular functions, seem to offer Utopian promises to the human geneticist But in reality there are very great difficulties in applying to man even the theoretical results derived from genetical analysis of animals, and until this is done any considerable attempts at the practical application of modern genetical methods of breeding must be considered premature In this book Prof Hogben confines himself to the preliminary question of a rigorous analysis of the genetical mechanism underlying the variability of human beings, and has left on one side the problems of its experimental modification His discussion of the methods of analysis is straightforward and enables the reader to form some estimate of the validity of the arguments, which one hears more and more frequently, proposing concrete eugenical reforms.

The human geneticist, since he cannot undertake any experimental breeding, must adopt analytical methods which are rarely employed in animal genetics, and which are therefore still in their infancy These methods are primarily statistical The general principle is to deduce, from the ascertained Mendelian laws, the proportions of different phenotypes which would be expected in the population on several different hypotheses, and then to decide which of these conclusions is best borne out by the facts Such a procedure was, of course, impossible until the general laws of heredity were thoroughly known and securely based on observations with animal material

It is always desirable, and frequently necessary, to develop and examine several different consequences of each hypothesis which it is desired to test The demonstration of the existence in man of rare recessive characters, which a geneticist would expect on general grounds, provides a good example of the kind of difficulty met with. If a character is determined by a rare recessive gene, some matings between an affected and a normal parent will give rise to affected offspring, the normal parent being in this case heterozygous for the gene in question, while other such matings will give no such offspring, the normal parent being homozygous dominant We can calculate the proportion, among all affected by normal matings, of those which give at least one affected offspring The formula depends on the frequency of affecteds in the population as a whole. When this formula is applied to the figures available for various abnormalities (such as albinism, p. 52 *seq*) it fails to fit

This failure may be due to the concentration of the gene for albinism in a small local section of the population, within which its frequency may be considerably higher than in the community at large Other tests must therefore be applied, and Prof Hogben discusses several possibilities On p 72 he investigates the expected proportion of affecteds normals among the offspring of matings between two heterozygous parents, and between a heterozygous and a recessive parent The animal geneticist expects, and obtains, a 3 1 ratio in the first case and a 1 . 1 in the second But, as usual, the human geneticist immediately finds himself in difficulties, because the only practicable way of differentiating these two types of matings from matings involving a homozygous dominant parent is the fact that they give rise to recessive offspring Now many human families are so small that statistical expectations are not realised, and the expected recessives may therefore not appear

Several methods, one of them due to Prof Hogben, are available for adjusting the expected ratios to include this complicating factor Even with these refined methods, however, it is not always possible to decide whether a given abnormality is inherited strictly as a Mendelian recessive, since in some circumstances it is impossible to distinguish between this hypothesis and the hypothesis that the character is dependent on the presence of both of two independent dominant genes Prof Hogben produces another weapon from his armoury to deal with such cases If a recessive gene is rare, that is, has not spread through the whole population, many of the heterozygous carriers of it will be descended from the same ancestors Marriages between such related individuals will, therefore, be more likely than random matings to produce affected offspring. Reversing this argument, it is possible to calculate what proportion of all recessives have related (for example, first cousin) parents (p 59).

This outline of the analysis of rare recessive characters has been carried far enough to show the difficulties which stand in the way of exact work in this field. It is no longer sufficient to identify the hereditary basis of human characters by purely qualitative considerations The study of human genetics will only advance when exact quantitative methods can be applied to a rich supply of data It is the particular merit of this book that it gives a short account of nearly all the most important techniques for exact work of this kind Some of these techniques are due to the original researches of Prof Hogben, but in this set of lectures he is more concerned to give an easy exposition of the principles involved than to provide mathematically unassailable derivations of the various formulæ The mathematics therefore are of the order which can be understood by most biologists who have no special training in this field The simplification of the calculations has been most successfully carried out, but the order in which the whole subject is treated is not so happy The matters dealt with in the first four-fifths of the book are complicatedly interwoven and a greater number of cross-references might have made it easier for the beginner to get his bearings

The fifth and last chapter deals with a rather different subject, namely, the problem of assessing the contributions of heredity and environment to the expression of a character Here again the author most happily lays the emphasis on the exact quantitative methods which are available, and this chapter contains the most critical short account of this problem which has appeared in Great Britain since the fundamental pioneer work of Fisher Prof Hogben comes to the conclusion that Fisher's treatment is invalidated by the fact that human individuals live in families, whence arises a correlation between the incidence of gene differences and environmental differences. If two different genetic stocks are kept in different environments, it is impossible to determine how much of the observed difference between them is due to the genetic difference and how much to the environmental difference. The question is in fact strictly meaningless. The eugenical and sociological importance of such conclusions is obvious, and this section of the book, though it makes no pretensions to finality, contains much which should be regarded as indispensable fundamentals in the eugenist's education.

The whole book can be heartily recommended to the attention of all those who are interested in the genetical basis of human variability with the assurance that, although it may need more effort to understand than some of the popular works on such subjects, the reader may have confidence that Prof. Hogben is leading him, not 'down the garden', but up the strait and narrow path of scientific rectitude.

C. H. W.

Modern Photochemistry

Grundlagen der Photochemie Von Prof Dr K F Bonhoeffer und Dr P. Harteck (Die chemische Reaktion, herausgegeben von H. Mark und M Polanyi, Band 1.) Pp viii+295. (Dresden und Leipzig Theodor Steinkopff, 1933) 24 gold marks

IN no branch of physical chemistry is there a greater danger of a divorce between theoretical treatment and experiment than is the case in modern photochemistry The adequate interpretation of band spectra even of the simpler diatomic molecules is a problem requiring no little mathematical skill and ability, a level not frequently attained by the experimenter The authors must be congratulated on producing a volume which, whilst written primarily for chemists, lays stress on the theoretical aspects of the subject. The book is divided into four sections, the first being devoted to the consideration of the Einstein law of photochemical equivalence, the two following to the primary and secondary photochemical processes, and the last to more complex cases of photochemical action

The difficulties which the chemist usually finds in understanding the complexities of atomic and molecular spectra when interpreted by the physicists are practically eliminated in the volume, a feature of which the authors should be proud. Frequent use is made of analogy, which renders the material not only extremely interesting but also very readable One of the most useful sections of the book deals with the behaviour of free atoms, a subject to which the authors themselves have been the chief contributors

The identification of the reaction products formed when hydrogen, oxygen or halogen atoms undergo reaction with simple substances has been the subject matter of investigations only of the last few years, and the collection and critical survey of the results obtained forms one of the most interesting sections in the book. It is clear that whilst some progress has been made in understanding the mechanism of the hydrogen-chlorine reaction, the hydrogen-oxygen reaction bids fair to provide us with a worthy substitute Whilst some would have cared to see the inclusion of a little more material on fluorescence and its quenching both in gases and in solution, the book must certainly be regarded as the best that has yet appeared on the subject

Science and Human Welfare

The Book of Scientific Discovery: how Science has aided Human Welfare. By Dr D. M. Turner. Pp. 259+31 plates. (London, Bombay and Sydney: George G Harrap and Co., Ltd, 1933.) 7*s.* 6*d* net

MISS DOROTHY TURNER (now Mrs. Féjer) has given us an admirable book which would serve well as a foundation for the teaching of the history of science in any school, and yet at the same time is mature and comprehensive enough to be welcome to any adult who does not despise the good things devised primarily for his juniors There is so much to praise that one hastens to discharge one's only grumble. It seems a pity not to have given the few pages which would have been necessary to introduce the work of the Greeks as the indispensable foundation As the book stands, no one would gather from it that the Greek work was indispensable; in fact, where a Greek is mentioned, it is only to point out that he made some mistake or at best a lucky guess We start in the first sentence by "living in the twelfth century", and "searching for what any ancient writer said" to enlighten our ignorance

It is of course right and necessary to insist on the need of constant criticism, and to show that, before the Renaissance, science had been languishing from want of fresh and accurate observation and from the slavish repetition of the errors of Aristotle and Galen. But the fault was Alexandrian and not Greek The Greeks, from whom we derive not only science but also the whole framework of our intellectual life, were critics *par excellence*, and their failure to go further on the path they first opened to mankind, was due not to intellectual apathy but to their too eager wits, to the lack of scientific instruments, to the want of co-ordination between science and industry, perhaps, most of all, to the prevalence of slavery and the slave spirit.

It is also of the first importance from the historical point of view which Miss Turner keeps so well in mind in the rest of her book, to recall both to scholars and teachers, that Western civilisation, of which science is now the chief instrument and leading feature, was founded and built up by the Greeks and their kindred in Rome. The joint work of Greece and Rome is the signal example in the world of the application of the scientific spirit to human affairs.

The merits of Miss Turner's book which most strike the eye, are its great clearness and accuracy of statement, and the way in which she manages to select interesting and significant facts to illustrate the most important turning-points in her story. Her account of Newton is a case in point, with its excellent sketches both of the prisms used in his optical experiments, and of the path of projectiles and of celestial bodies to illustrate gravitation

It is also a great merit to have divided the matter so well into its natural periods Newton's work leads directly to the application of mechanical powers to industrial production. Then comes a chapter on "Science as a Factor in Social Change", in which is included the beginnings of a scientific policy in public health This, as the author rightly sees it, is an integral part of the industrial system, which by grouping the workers in large town communities, enforced the public control of their living conditions and brought on State action both in health and education Subsequent to this she places the beginning of an age in which chemistry became the leading science, to be followed with one, which we are now entering, when biological discoveries have a dominating influence on our ways of thinking She is right to place this last, and right also to deal with it in rather a more summary fashion, as, being herself a teacher on the physical side of science, she is able on that to speak with greater fulness and sureness in detail The biological chapters are, however, perfectly competent and fit in well with the rest. Several authorities, including Prof. Charles Singer and Prof Frankenberg of the Department of Histology in the University of Bratislava (Czechoslovakia), have given adequate assistance in various ways

It is not surprising, in view of the social spirit which inspires the whole book, to find that the author ends with a sound appreciation of the boons which science has conferred, especially on the masses of the workers, and in spite of the added dangers in war and the loss of quiet and natural beauty which have undoubtedly to be reckoned on the debit side. Unfortunately, too many of us are inclined to dwell rather on the evils than on the good which far outweighs it. Such people may be advised to read Miss Turner's concluding pages. She points out that the spread of science is essentially a popular cause. Before the industrial revolution, "for one happy craftsman there were thousands of starving beggars". The good things of life were far less widely distributed.

"Applied science has relieved man from grinding toil. Leisure is more widespread and appreciation of art and learning no longer confined to the very few. . . . Science bids us take a long view of time." But also a hopeful one. If after the lapse of a few hundred years with their blunders, national jealousies and wars, we have been able to accomplish so much, what may not the future bring, if we have but the common-sense to work together ?

F. S. MARVIN.

Short Reviews

Plant Parasitic Nematodes and the Diseases they Cause. By Dr. T. Goodey. Pp. xx+306. (London : Methuen and Co., Ltd., 1933.) 21*s*. net.

DR. GOODEY has for more than twelve years carried out investigations on eel-worms, and his special qualifications have enabled him to produce this practical account of parasitic plant nematodes with its admirable illustrations. He describes the general structure of a nematode and the technique of preparing these worms for microscopic examination and explains the significance of the formulæ originated by Cobb and refers to certain matters of nomenclature which affect the names of the worms. He then passes to the consideration of the species of *Anguillulina* which cause galls or are otherwise parasitic on shoot structures or are parasitic on roots. In succeeding chapters the species of *Heterodera* which parasitise roots and the species of *Aphelenchoides* are considered, and a chapter is devoted to plant nematodes which are parasites and semi-parasites of doubtful pathogenicity, to saprophytes and to predators.

The usual treatment of each species is to give first a summary of the results of researches upon it, then to state the characters of both sexes and of the eggs and larvæ, to trace the life-history, to note the usual hosts and the symptoms produced in them by the attacks of the parasites, and to refer to the pathology of the plant tissues affected by the worm. The geographical distribution of the worm is stated and the methods of control are concisely described. A final chapter is devoted to the presentation of data on the existence of biological races in two species of plant parasitic nematodes. The evidence presented shows that, for example in *Anguillula dipsaci*, there exist unspecialised polyphagous races, also races which are more specialised and are able to attack few hosts, and other races which are highly adapted and can live on only one or two host-species.

The author is to be congratulated on the sustained lucidity and practical outlook of his book, qualities which will ensure for it a welcome from zoologists and plant pathologists.

The Wright Encyclopædia of Gardening. By Walter P. Wright. Pp. xvii+624. (London and Toronto: J. M. Dent and Sons, Ltd., 1933.) 15*s*. net.

THOSE who have known, and used with profit, the "Everyman Encyclopædia of Gardening", will be interested in this new and greatly enlarged development of those two handy volumes. After a sketchy chapter entitled "Introductory Memoranda" there follows a good and well-illustrated glossary of terms. The main substance of the book consists of an alphabetical list of plants and gardening operations, including larger articles on specific sections such as annuals, fruit orchards, herbaceous borders, vegetables and so forth. Subsequent chapters include a gardening calendar, that 'hardy perennial' so invariably found in any book on gardening in general, an "Outline of Garden Science" in which the elementary physiology and anatomy of the growing plant is presented in a brief but adequate form, an article on "Home Landscape Gardening", which might well have been included in the main text, and finally a chapter on the making of garden structures such as green-houses and frames, summer-houses and numerous rustic articles.

As a convenient reference book which is not too large to handle with comfort the publication can be recommended, but it is to be hoped that in the next edition some major errors of omission and commission will be corrected. For example, under diseases of apples we find the statement that ammonium polysulphide is a "good remedy" for "Bitter-pit"—a purely physiological affection of apples in store. Again, it is surprising to be told that "nitrogenous fertilisers are valuable according to the amount of ammonia they yield", one of the most widely used nitrogenous fertilisers, nitrate of soda, is rarely assessed in terms of ammonia. Yet one other example, any treatment of the subject of tomato cultivation is incomplete without reference to the *Encarsia* parasite of white fly. With such a simple method of control of that troublesome pest available to anyone, it is scarcely wise to recommend to amateurs the troublesome and dangerous method of fumigation with hydrocyanic acid gas.

The Testing of High Speed Internal Combustion Engines : with Special Reference to Automobile and Aircraft Types and to the Testing of Automobiles. By Arthur W. Judge. Second revised and enlarged edition. Pp. xvi+459+84 plates. (London: Chapman and Hall, Ltd., 1932.) 25*s*. net.

THIS is a revised edition of a book first published nine years ago. In its original form it gave a full and uncritical account of the many ways there are of testing high-speed internal combustion engines on the test bed, on the road, or in the air. It also described the numerous pieces of ingenious mechanism necessary for carrying out these tests. The present volume adds to this earlier account, but the same remarkably inclusive—and uncritical—plan has been followed

The most interesting of the additions is an account of the wonderful Rolls-Royce engine used for the British Schneider Trophy seaplanes and its manner of test. The author describes how this engine of but 34 litres cubical capacity, giving in its original form 825 h p., was so skilfully modified as to yield no less than 2,300 h p —an increase from 25 h p per litre to no less than 68—with an increase of speed of as much as 1,000 r.p m beyond that of the parent engine

As illustration of the immense ingenuity of modern testing methods, the author mentions the discovery of hair cracks in connecting rods by the painting of the rod after magnetisation with fine iron filings carried in paraffin, and the revealing of cracks in aluminium pistons by oil marks on a dusting of powdered chalk It must be confessed that the text is on occasion obscure One example will suffice the author wishes to say that the capacity of an exhaust silencer must be twenty times the cylinder-swept volume, what he does say is that the capacity of the silencer in cubic feet must be eighty per cent of the cylinder capacity in litres Despite these occasional lapses the book will prove of real value to those engaged in the testing of this prime mover

Suns and Worlds an Introduction to Astronomy By W H Steavenson (The How-and-Why Series) Pp. 104+4 plates (London: A. and C Black, Ltd, 1933) 2*s* 6*d* net

As was to be expected of one who is himself above all a diligent observer, Dr Steavenson has written a book in which the actual appearance of the heavens is given considerable prominence The last few years have seen a number of books on popular astronomy, but the present volume has a great deal to recommend it, partly on account of this circumstance One of the difficulties which beset the writer of popular expositions is the choice of a mental standard for his public, the author must make up his mind whether he is addressing an intelligent schoolboy, a casually interested adult, or an enthusiastic and painstaking reader Dr Steavenson starts off by explaining the seasons and the phases of the moon, but he goes right on to give an account of galactic rotation The mathematics is suppressed, but the general line of the argument is sometimes given Judging by the phases of the moon, which we usually see expounded in fairly elementary school-books, Dr Steavenson has chosen for his public the intelligent schoolboy. and judging by the rotating galaxy—but why not the schoolboy too? There is a lot to be said for astrophysics as an academic exercise for the young, and it is a pity that it is not a school subject. Astrophysical work involves a peculiar mixture of mathematical and general reasoning, and would provide an excellent mental gymnastic. But this is a digression; Dr. Steavenson is out to interest more than to instruct, and in this we can have no doubt but that he has succeeded.

The Methods of Cellulose Chemistry. including Methods for the Investigation of the Compound Celluloses By Dr Charles Dorée Pp x+499. (London: Chapman and Hall, Ltd, 1933.) 21*s*. net.

THE title of this book and the name of the author provide an indication of an excellence which is not belied by its contents. Dr. Dorée has, in fact, succeeded admirably in his stated object of providing a collection of the best available methods for the experimental investigation of cellulose and of its associates and derivatives. He has achieved this by drawing lavishly, but with discretion, on the literature of chemistry, physics, botany and biochemistry, and on the technical side, from journals dealing with textiles, paper, dyeing and colloids, and he has supplemented this information by his own original work and tests of the methods concerned Theoretical discussion of experimental data is, perhaps wisely, avoided

The methods are classified in three sections dealing with normal cellulose, its synthetic derivatives and compound celluloses The latest developments in determinations such as of viscosity, of degradation products of celluloses and of α-cellulose are treated fully, and will make special appeal to the worker in industry, who in the past has usually had to build up a composite method of his own from the numerous published alternatives The section on woods neglects some important work carried out in Australia which will probably result in fundamental modification of the methods of wood analysis J. G.

Analytic and Vector Mechanics By Prof. Hiram W. Edwards. (International Series in Physics) Pp x+428 (New York McGraw-Hill Book Co, Inc, London McGraw-Hill Publishing Co, Ltd, 1933) 24*s*. net

THIS useful work is well adapted for students entering upon a university honours course The notation and fundamental principles of vector analysis are fully explained, and vector methods are freely though not so forbiddingly employed as to repel a generation which still finds it easier to think in terms of Cartesian methods than to apply a vector calculus *ab initio*

After chapters which deal with velocity and vectors, the author develops the subject by way of the traditional topics handled clearly and skilfully Harmonic motion, the dynamics of translation and rotation, elementary statics (including attraction and potentials), central forces, particle motion in fluids with resistance, and damped harmonic motion—these headings give a conspectus of the principal topics leading to chapters on vector fields, precessional motion, Lagrange's equations and Hamilton's principle. Physical applications are kept well in the foreground, and, while the treatment of such fundamental physical problems as the definition of mass might very well be extended, junior honours students in physics will find the book reasonably well suited to their needs. A. F.

The Positron*

By DR CARL D ANDERSON, California Institute of Technology, Pasadena, Calif

THE existence of free positive electrons or positrons was first reported by me in September 1932[1], from cosmic ray experiments carried out at the California Institute of Technology In the original paper, all possible alternative interpretations of the effects there presented were discussed in detail, and it was shown that only by calling upon the existence of free positive electrons could those effects be logically interpreted

As a part of Prof R A Millikan's programme of cosmic ray research, in particular to make energy measurements of the cosmic ray particles by the use of a vertical cloud chamber in a very powerful horizontal magnetic field, photographs were first taken in August 1931 in such an apparatus involving the maintenance of a field of strength up to 20,000 gauss over a space measuring 17 cm × 17 cm × 3 cm As reported in lectures in Paris and Cambridge, England, in November 1931 and published in March 1932 by Millikan and myself[2], this work brought to light for the first time the fact that nuclear effects are of primary importance in the absorption of cosmic rays, as demonstrated by the frequent occurrence of associated tracks or showers containing particles of positive charge as well as those of negative charge

Through the insertion in May 1932 of a lead plate across the centre of the cloud chamber, it was possible to show definitely in several cases that the mass of these particles of positive charge could not possibly be as great as that of the proton The direction of motion of the particles was given in two ways: first, by allowing them to pass through the lead plate and suffer a loss in energy, and secondly, by the observation in several instances of two or more tracks all originating at one small region in the material surrounding the chamber For a given curvature of track, the specific ionisation showed that the mass was small compared with the proton mass, but even more definite evidence was gained from an observation of the range of the particles. The observed ranges were several times, in some instances more than ten times, greater than the possible ranges of proton tracks of the same curvature.

These considerations were the basis of the report announcing the existence of the free positive electron or positron published in September 1932. Within the next five months a large number of confirmatory photographs revealing unambiguously the existence of positrons was taken, and a second report was published in March 1933[3] in which fifteen of these photographs were discussed. The specific ionisation exhibited by the positron tracks on these photographs showed that the magnitude of charge of the positron could not differ by as much as a factor of two from that of the free negative electron, and it was, therefore, concluded, unless one admits fractional values of the elementary unit of charge, that the free positive and negative electrons were exactly alike in magnitude of charge This fact, together with the curvatures measured in the magnetic field of a positron before and after it penetrated a plate of lead, fixed its mass as not greater than twenty times that of the free negative electron

Since then[4], an observation of a collision between a moving positron and a free negative electron in the gas of the chamber revealed, on the basis of the conservation laws, that its mass was equal to that of the free negative electron with an error of not more than 30 per cent. More recent measurements[13] of the specific ionisation of the positives and negatives for both high and low speed particles, by actual ion-counts on the tracks in the magnetic field, showed the specific ionisation of the positives and the negatives to be equal to within 20 per cent This fixes the limits of difference between the positives and negatives with regard to their charges and masses at 10 per cent and 20 per cent respectively Further details of the history of this discovery were presented at the American Association for the Advancement of Science meeting in Chicago in June 1933[4]

In March 1933 confirmatory evidence for the existence of positrons was presented by Blackett and Occhialini[5], based on similar experiments with a vertical cloud chamber operating in a magnetic field of 3,000 gauss and actuated by the responses of Geiger-Muller counters In April 1933 Chadwick, Blackett and Occhialini[6], Curie and Joliot[7], and Meitner and Philipp[8] reported that the bombardment of beryllium by α-particles can produce radiation which results in the production of positrons, though in these experiments it was not possible definitely to identify the nature of the radiation producing the positrons By absorption experiments, however, Curie and Joliot showed that the yield of positrons decreased approximately as was to be expected if the γ-ray rather than the neutron component of the radiation were responsible for their production.

The first experiments proving directly that a γ-ray photon impinging upon a nucleus gives rise to positrons were carried out at the Norman Bridge Laboratory, using the γ-rays from thorium C'', and reported in April 1933[9] In this paper the fact that free electrons of both positive and negative sign are produced simultaneously by the impact of a single γ-ray photon, an observation of considerable theoretical import, was first presented Preliminary results of energy measurements were given in June 1933 by Neddermeyer and myself[10] Curie and Joliot[11] in May 1933, and Meitner and Philipp[12] in June 1933, all of whom used γ-rays from thorium C'', also reported the detection of positrons from the same source. Curie and Joliot[13] have also shown that positrons are produced directly in the disintegration of aluminum and boron by α-particle bombardment. The positrons in the case of aluminum cannot here be produced by the internal conversion of a γ-ray photon unless the probability of such internal conversion is vastly greater than that to be expected on theoretical grounds[14] Rather do these experiments indicate that an elementary positive charge is actually removed from the disintegrating nucleus and appears as a positron

---

* Address delivered at the Symposium on Nuclear Physics of the American Physical Society meeting in Boston, Mass, on December 27, 1933

The foregoing furnishes in brief a historical survey of the early experimental work on positrons and their production

A detailed study of the energy distribution and frequency of production of free positive and negative electron pairs by filtered thorium C″ γ-rays is of particular value because of the relative simplicity of these effects as compared with those appearing in the cosmic ray range of energies

γ-RAY EFFECTS

A discussion will now be given of experimental evidence as it bears on the theory suggested by Blackett and Occhialini on the basis of the Di electron theory, which postulates the creation of a free positive-negative electron pair out of the absorption of a photon impinging upon a nucleus The nucleus itself in this picture undergoes no disintegration, but plays merely the rôle of a catalytic agent. This discussion will be given in the light of (1) new statistical studies by Neddermeyer and myself on the thorium C″ γ-ray effects, and (2) new experiments on cosmic ray showers by Millikan, Neddermeyer, Pickering and myself

The work of Curie and Joliot, and of Chadwick, Blackett and Occhialini on the radiation from thorium and that excited in beryllium by α-particle bombardment, together with our own work on the cosmic radiation[15], has shown that the absorption process which gives rise to positrons becomes increasingly important with high energy radiations and heavy absorbing materials Further, we have made a statistical study based on a total of more than 2,500 tracks of single electrons, both positive and negative, and positive-negative pairs ejected from plates of lead, aluminum and carbon by γ-rays from radiothorium filtered through 2·5 cm of lead (in some cases with unfiltered rays for comparison) to determine the frequency of occurrence of pairs and single positrons, and their energy distribution for absorbing materials of different atomic numbers The ejection of the particles was observed from lead plates of 0·25 mm thickness, aluminum plates of 0·5 mm. thickness and a graphite plate of 1·4 cm thickness (used also for cosmic ray studies) The magnetic field was here adjusted to 825 gauss

We will consider first of all the energies. Both the single positives and the pairs (the sum of the energies of the positive and negative components being taken) ejected from the lead plates showed a maximum energy of about 1·6 *MV* (*MV* = millions of electron-volts), 80 per cent of the single positrons having an energy less than 0·8 *MV*. For the case of the unfiltered γ-rays, the positrons and the pairs, though occurring in relatively fewer numbers compared with those ejected by the filtered rays, showed also a maximum energy of 1 6 *MV* Further, in the case of the positives and pairs ejected from the plates of aluminum, the maximum energy was about 1·6 *MV*

The maximum energy of the single negative electrons in all cases was about 2·5 *MV* Since the errors in the energy measurements may be as high as 15 per cent, this is in good agreement with the highest energy to be expected for extra-nuclear electrons resulting from Compton encounters or photoelectric absorption of the 2 65 *MV* photons.

n energy of 1 6 *MV* for the positives and the pairs, both from the lead and the aluminum, is in good accord with that to be expected on the Dirac picture if 1 *MV* is allowed for the energy required to create a pair of electrons. There occurred, however, one pair the total energy of which was 2·9 *MV*, it is conceivable, though not likely, that it may have been produced by cosmic rays, or again it may represent the rebound of an electron against the under surface of the lead plate

Of equal importance with the distribution in energy is the distribution in number of single positive electrons and pairs as compared with the single negative electrons Out of a total of 1,542 electrons ejected from the 0 25 mm. lead plate by γ-rays from radiothorium filtered through 2·5 cm of lead, there were 1,387 single negatives, 96 single positives and 59 pairs From an aluminum plate 0·5 mm thick and ejected by the same radiation there were, out of a total of 943 electron tracks, 916 single negatives, 20 single positives and 7 pairs.

The negatives may be assumed to have arisen in general from Compton and photoelectric encounters with extra-nuclear electrons in the lead or aluminum. But the single positives and the pairs must all, of course, correspond to nuclear encounters If we assume that on the average an equal number of positives and negatives results from nuclear impacts, we can calculate the ratio of the nuclear to extra-nuclear absorption This amounts to about 20 per cent for lead and about 50 per cent for aluminum. These values are in reasonably good agreement with those obtained by Chao[16], Meitner[17] and Gray and Tarrant[18] by entirely different methods in the matter of the excess absorption shown by lead over that shown by aluminum and also in the general relation of nuclear to extra-nuclear absorption in both metals.

That the nuclear absorption in carbon is very small for the thorium C″ γ-rays is shown by the fact that, as compared with 415 negatives, there appeared only 2 pairs and 6 single positives

On the whole, the energy relations of the positives and pairs, from both the aluminum and the lead, appear to be quite consistent with the pair-creation hypothesis, as are also the approximate values of the excess absorption in lead and aluminum calculated on this assumption.

The ratio of the observed numbers of single positives compared with the pairs is also of great importance in this connexion Whether a positive is always formed paired with a negative, or whether a positive not accompanied by a negative can in some cases be produced, is a question difficult to answer from the data so far obtained. An accurate calculation of the probability of removal of the negative, if a pair is generated, so that only the positive emerges from the plate, is not simple to make, depending as it does on energy loss and plural scattering in the plate, and on the initial space and energy distribution of the components of the pairs But on the basis of very approximate considerations, it appears somewhat difficult to reconcile the appearance, for example, in the case of aluminum, of 20 single positives and only 7 pairs with the view that they are always formed in pairs Experiments now planned in which the particles are ejected from very much thinner plates should decide this question

One case should be cited in which two negatives and two positives were all observed to originate at one point in the lead plate The possibility that this can represent two pairs accidentally associated in time and position is so remote that it is taken as evidence that *photons of energy even so low as those of the thorium C'' gamma-rays can occasionally give rise to showers such as are a common feature of the cosmic rays*[9].

COSMIC RAY EFFECTS

Our recent stereoscopic photographs taken in a 17,000 gauss magnetic field show numerous showers of more than thirty electrons, some positives and some negatives, originating in lead plates placed across the chamber. In all the observed cases of shower production, it was clearly seen from the photographs that non-ionising particles produced the showers. Also photographs taken in a magnetic field of only 800 gauss showed many examples of single negatives, single positives, pairs and triplets, of energies of the order of only a million or two electron volts, ejected from plates of lead by the impact of non-ionising particles These low energy ejections are in all respects identical with those produced by the thorium C'' γ-rays and are undoubtedly due to low energy photons. These electron effects cannot be ascribed to ordinary neutrons since a considerable study of neutrons in this very range of energies has shown that their absorption results in projected nuclei and not in electron projection or shower formation. The appearance of several such small electron showers on one photograph which contains evidences of showers which occurred above the chamber, brings to light a new fact, namely, that *in the absorption of the cosmic rays there are produced, in addition to the electron showers, in some instances, sprays of large numbers of secondary photons.* The evidences for this conclusion were presented at the November 1933 meeting of the National Academy of Sciences by Millikan, Neddermeyer, Pickering and myself[10], and a full discussion together with the photographs will appear shortly in the *Physical Review*. In one case, more than eighty low energy electron tracks simultaneously projected were photographed, their positions and orientations in the chamber showing that they must have arisen from nearly as many separate centres in the material surrounding the chamber, and must therefore be ascribed to such a spray of secondary photons

That pair production or shower formation by a fast electron (positive or negative) is a relatively rare event is shown by the fact that more than a thousand fast electrons have been observed to traverse a 1 cm lead plate, and only in one instance was a definite pair projected from the lead by a fast electron, while a large number of secondary negative electron tracks appeared as the result of close encounters with the extra-nuclear electrons in the lead plate The immediate secondaries of fast electrons are therefore seen to consist largely of negative electrons and only in rare cases of positrons

Because of the powerful magnetic field we are using, it is possible to deflect all but a very small number of the electrons projected in the showers by the photon impacts In general, in a shower a pronounced asymmetry is noted in the numbers of positive as compared with negative electrons emerging from the lead plates, in one instance 7 positives and 15 negatives, and in a second case 15 positives and 10 negatives These effects are only with some difficulty reconciled with the Dirac theory of the creation of pairs out of the incident photon Rather might they indicate the existence of a nuclear reaction of a type in which the nucleus plays a more active rôle than merely that of a catalyst, as for example the ejection from it of positive and negative charges which then appear in the showers as free positive and negative electrons. The essential difference, however, between these two points of view may be merely that in one case the nucleus may change its charge, and in the other it does not do so

To study nuclear absorption in a light element, more than four hundred successful photographs were taken in which a carbon plate of 1·4 cm. thickness replaced the lead plate. Many of these showed showers originating in a block of lead placed above the chamber, but in no instance was a secondary shower observed in the carbon plate. This indicates, in agreement with the thorium C'' data, the relatively small probability in comparison with lead of a carbon nucleus absorbing a photon by shower production.

A consequence of the pair-theory is that, in a suitably dense environment of negative electrons such as obtains in ordinary matter, a positron shall have a high probability of combining with a negative electron, resulting in the annihilation of both particles and the conversion of their proper and kinetic energies into radiation. The theory, though at present incomplete, states that the mean free path for annihilation is in general greater than the range of the positron, so that such annihilation should be evidenced by the appearance of quanta of about half a million electron-volts energy and a very small number of quanta of about one million electron-volts energy when positrons pass through matter[20] The experiments by Gray and Tarrant[18] on the scattering of thorium C″ γ-rays showed the existence of secondary radiation of such energies, but some of the more recent experiments on the scattering of hard γ-rays fail to show a secondary radiation which can be attributed to the annihilation of positrons Our cosmic ray photographs show that in the electron showers there are present large numbers of secondary photons, many of which are in this range of energy, but it is not yet certain if they are produced in part by the annihilation of positrons In two very recent papers, Joliot[21] and Thibaud[22] report the observation in experiments with artificially produced positrons of secondary photons of the energies to be expected if they arise from the annihilation of positrons By control experiments with negative electrons, they showed that a beam of positrons impinging upon matter results in the production of a considerably greater quantity of photons than does an equal number of negative electrons.

Research in the Cotton Industry

IN a discourse entitled "Industrial Research A Business Man's View" delivered at the Royal Institution on December 15, Sir Kenneth Lee made some striking references to the place of research in industry, based largely on the actual experience of Messrs Tootal Broadhurst Lee and Co , Ltd Up to twenty-four years ago, they had no scientific staff connected with the business, and it was only experience gained during the War which induced them to make a direct attack by means of research on the production of cotton material like wool in its power to resist and recover from creasing Sir Kenneth proceeded to outline briefly the steps which after fourteen years' work had enabled them to market successfully a creaseless cotton fabric

The initial step was the assembling of the nucleus of a research staff in the belief that, even in such an old-established industry as that of cotton, research could be of immense advantage, systematic work on the chemical and physical properties of cotton or on the physical basis of the machine processes to which it was subjected in the course of manufacture should greatly facilitate uniform and steady progress. Alluding to the lack of such systematic work in the cotton industry, Sir Kenneth cited the process of mercerisation Although Mercer discovered in 1844 that caustic soda had a marked action on cotton, it was nearly fifty years later when Lowe discovered how the conditions must be modified to produce lustre by mercerisation, while Mercer's discovery itself did not attract the active interest of academic scientific workers

In its progress from the bale, through spinning, weaving, bleaching, dyeing and finishing, cotton is subjected to various physical and chemical processes It was therefore decided, when the Research Department was formed, that the staff should consist of chemists and physicists who should work together on the problems involved, and when a laboratory solution had been found, should share their knowledge with technical men in an endeavour to harvest their results in manufacture This was the first time that chemists and physicists had been engaged in co-operation in the cotton industry It was also decided that lack of experience in dealing with cotton should be no bar to the engagement of any member of the staff Provided ability to conduct research was evident, this lack of experience was even regarded as an advantage, since such workers would not have got into ruts and would be more likely to contribute a fresh outlook on the problem.

In addition to the decision to adopt a definite research objective, the further important initial decision was made to carry out routine testing by a separate staff, housed in the same laboratory, so as to provide the maximum contact between the research staff and the analytical or testing staff. The wisdom of the policy embodied in these preliminary decisions is attested not only by the results achieved by the Tootal Broadhurst Lee Co , Ltd , but also by the experience of numerous other industrial research organisations in Great Britain and in other countries

Most of the published work on cotton had previously been concerned with large-scale experiments on yarns and fabrics. In view of the dependence of the physical behaviour of such materials not only on the yarn comprising them but also on the weave, on the twist and diameter of the yarns and the nature of the innumerable cotton hairs, it was decided to commence by investigating the properties of the cotton hairs themselves, the fine fibres about an inch long and a few *ten-thousandths of an inch in diameter* from which all cotton yarns are made. Special apparatus was devised to compare the elastic properties of the various textile fibres in air and in various liquids, and the sponginess of the hairs proved to be of great importance.

It was early realised that there are at least two methods of attacking the creasing problem. One is to fill the spongy cotton hairs with some elastic substance; another is to combine with the cotton some substances which would eliminate its plastic nature and give it the necessary resilience. Both methods were tried and finally the introduction of synthetic resins into the fibre proved successful, though only after some years of work had shown the way to retain all the other textile qualities of cotton when it was impregnated with resin. To be suitable for this purpose, the synthetic resin molecules should be small during the impregnation of the fabric so as to enter the cotton hairs. The substances used must not damage the fabric nor must resinification by heat or otherwise be effected under conditions which damage the fabric. Furthermore, the resin must be colourless and not discoloured by strong sunlight; it must be elastic so as to give the anti-creasing properties, and must be introduced without impairing the suppleness of the fabric. It must also withstand laundry treatment.

These conditions considerably limited the types of resin which could be used. Further investigation showed that when the resin was mainly inside the cotton hairs a soft fabric was obtained, but when a considerable amount of resin was left between the hairs and the yarns, the cloth was hard and stiff. The microscopic examination also showed that the diameter of the cotton hairs is permanently increased, causing the fabric to give better cover, and the treatment accordingly must be directed towards getting rid of all the resin between the fibres. By treating cotton and rayon fabrics in this way, effecting final condensation after the resin solution was put on the cloth, remarkable anticreasing properties were conferred. In addition, shrinkage by washing was reduced while the strength of rayon was increased by 30 per cent when dry and up to 100 per cent when wet.

The next stage of development, from the laboratory to a manufacturing scale, proved difficult as well as costly. In addition to mechanical difficulties, physical and chemical methods of control at each stage of the process had to be elaborated. Not merely the design of suitable machinery, but also the development of suitable testing methods for accurate control made demands on a combination of engineering, chemical and physical knowledge which the man with a general training was often better able to meet than a highly specialised research worker.

One of the major difficulties was concerned with an apparatus for converting the resin inside the cotton hair into insoluble form. This had to be done by running a continuous length of cloth through a machine capable of heating it evenly over its width for a short time to a high temperature. Finally an electrical method was selected, which was novel in the electrical trade, and with this machine a production of some thousands of yards sufficed to gain the experience for the design of full scale plant in which weakness of design and lack of robustness in various details were eliminated.

Discussing the successful conclusion of this research directed to a definite objective, Sir Kenneth Lee raised the question as to how much stronger our industrial position might be as a result of more well-directed research. Patents themselves indicate the extent to which our research activity is overshadowed by that of competitive countries. Even most of our newer industries are handicapped by paying heavy tribute to foreign countries in the forms of licences, and from the results achieved by his own company Sir Kenneth said that they would be glad to see other industries, particularly the older industries, pursuing the same policy to a much greater extent. He considers that the present time is opportune for a great increase in the amount of scientific research in industry, and reduced expenditure on research in other countries offers us a correspondingly greater chance of taking the lead. Researches directed to putting manufacture on a sound scientific basis would undoubtedly repay the expenditure of time, money and patience involved, and the nations doing the most intelligent research work are likely in the long run to have the greatest chance of prosperity. We have in Great Britain the necessary ability for fundamental research if only the business community would supply sufficient funds, and Sir Kenneth urged that there is no wiser expenditure for an industrial undertaking than the provision of funds for research.

Obituary

DR D. H. SCOTT, F.R.S.

WORKERS in the fields of natural knowledge are often described as pioneers in the development of novel views, as men whose enthusiasm was stirred in early life by the preaching of a new doctrine. Dukinfield Henry Scott's early days coincided with an intellectual revolution. He was born on November 28, 1854, a few years before the publication of the "Origin of Species", and graduated from Christ Church in 1876 at a time when men were under the influence of a new gospel. He died on January 29, 1934.

Following the example of other young men of that generation, Scott went to the famous botanical school of Sachs at Würzburg, where he took the Ph D degree On his return in 1882 he took a prominent part as a lecturer and later as assistant professor in applying modern methods at University College, London A member of a family of distinguished architects, he was attracted to the works of Nature rather than to the works of man throughout life he experienced the joys of a true naturalist From 1885 he occupied the chair of botany at the Royal College of Science until 1892, when he accepted an invitation from the Director of the Royal Botanic Gardens, Kew, to be honorary keeper of the new Jodrell Laboratory; two years later he was elected fellow of the Royal Society

Scott's earliest papers, the first of which was published in 1881, were on the latex-bearing vessels in certain rubber trees, on Algæ, and on the anatomy of *Ipomœa*. His last paper was published in 1933. Throughout life his botanical interests were wide and progressive while faithful to the traditions of the older school of naturalists and great systematic botanists, he devoted himself mainly to the investigation of extinct plants, particularly those from the forests of the Coal Age. In an address delivered in 1909, when, as president of the Linnean Society, he opened the new botanical laboratories at University College, London, he spoke of the late Prof W. C. Williamson as a friend to whom he perhaps owed more than to any other man, as it was Williamson who interested him in the subject of fossil botany

The veteran botanist at Manchester had contributed nineteen memoirs on "The Organization of the Fossil Plants of the Coal-Measures" to the Royal Society (1871–93), but comparatively few botanists in Great Britain realised the full significance of Williamson's work, and this was largely due to the presentation of the results in language unfamiliar to students whose sense of proportion and appreciation of values suffered through inability to make allowances for old-fashioned terminology and ideas On his retirement from Manchester, Williamson asked Scott to collaborate with him and, fortunately for the botanical world, a favourable reply was given. In a prefatory note to the first of a series of three memoirs—"Further Observations on the Organization of the Fossil Plants of the Coal-Measures"—Williamson wrote. "My morphological enquiries seem to have reached a stage that makes a more minutely careful examination of these questions of development and growth desirable, but before specially undertaking this, I saw clearly the extreme importance of doing so in combination with some younger colleague whose familiarity with the details of the physiology of living plants was greater than my own." The conspicuous success of this partnership is evidence of the tact and understanding of the younger man and of the confidence and respect for his companion on the part of an experienced palæobotanist who did not readily change his opinions. Scott's transforming influence was the determining factor in bringing about a more general recognition of the fundamental importance of extinct plants

After Williamson's death in 1895, Scott contributed a series of papers to the Royal Societies of London and Edinburgh, to the *Annals of Botany* and other journals, in which he described many new types. In 1897 he gave an exhaustive account of a remarkable cone, *Cheirostrobus*, which demonstrated the existence in the early part of the Carboniferous period of a reproductive shoot more complex in structure than any previously known vascular cryptogam, recent or extinct This was followed by equally interesting discoveries of many other Palæozoic plants In 1901 Scott gave an account of a cone—*Lepidocarpon*—agreeing in the plan of its construction with the cone of a *Lepidodendron*, but differing in bearing 'seeds' in place of ordinary sporangia. The seed-like bodies were described as nascent seeds which did not and could not be expected to conform "in all the morphological rules that we lay down for seeds at the present day" Scott was not a hide-bound formal morphologist

In all his many contributions to a more exact and intensive knowledge of extinct plants, Scott combined an almost meticulous attention to detail with broad philosophical and cautious views on the bearing of the facts on evolution In 1900 he published as a single volume a course of lectures delivered at University College, London—"Studies in Fossil Botany". in the second and third editions the book is in two volumes. The author's aim was the presentation to botanical readers of results which appear to be of fundamental importance. This book has long been a classic, a scholarly work distinguished by well-balanced judgment and clarity of style In 1911 he contributed to the "Home University Library" a more popular account of the "Evolution of Plants", and this was followed in 1924 by the publication of a course of lectures delivered at Aberystwyth—"Extinct Plants and Problems of Evolution".

In 1904, following a most important discovery by Prof F. W. Oliver that certain seeds known as *Lagenostoma* belonged in all probability to the genus *Lyginodendron*, a plant in habit and in foliage closely resembling a tree-form, a paper was published by Oliver and Scott in which the name Pteridospermeæ was proposed for a group of certain fern-like seed-bearing plants which played a dominant part in later Palæozoic and, as we now know, in early Mesozoic floras. For several years Scott regarded the Pteridosperms as closely related to true ferns and derived from a fern ancestry In 1918 he wrote (in a letter): "I have become a bit sceptical about the Pteridosperms and Ferns; all the comparisons seem to be mere analogies"; at the Bournemouth meeting of the British Association in 1919 he definitely gave up the idea of a fern origin in favour of the view that Pteridosperms represent a long-extinct stock which passed through a fern-like stage. This change of view is characteristic of the man: when, as rarely happened, the weight of evidence was against his original opinion, he did not hesitate to say so.

Scott's influence was by no means confined within the limits of palæobotanical research his "Introduction to Structural Botany", an elementary textbook in two volumes, Part 1 of which is now in its eleventh edition, is a model study of representative examples of flowerless and flowering plants. Mr F T. Brooks of Cambridge is associated with Dr. Scott as joint author of the last edition of both parts

In 1921 Scott was the Wollaston medalist of the Geological Society of London, in 1906 he received a Royal medal and in 1926 the Royal Society awarded him the Darwin medal In 1921 he was awarded the Linnean medal of the Linnean Society He was president of the Linnean Society in 1908–12 and of the Royal Microscopical Society in 1904–6, foreign secretary (1912–16) of the Royal Society, twice president of Section K (1896 and 1921) and a general secretary (1900–3) of the British Association. He was an honorary LL D of the University of Aberdeen and D Sc. of the University of Manchester, also honorary member or corresponding member of many foreign academies and societies

Though neither by inclination nor temperament attracted to administrative work, Scott conscientiously discharged such duties as he felt called upon to undertake · he was essentially a student, a dreamer with a 'passion of the past'; a man with strong international sympathy and a keen sense of justice. On occasion impulsive, quickly roused by unreason, a man of lovable personality to those who knew him well Few men of his age made a stronger appeal to the affection and loyalty of colleagues Scott will be gratefully remembered by many younger men and women whom he treated as equals It is fortunate that he was able to devote the best years of his life to research without the hampering necessity of spending the greater part of his energy in teaching

Scott was happy in the companionship of a wife whose personal qualities were complementary to his own from her he had much help in his work both directly and indirectly He leaves four daughters: his younger son died at school (1914) and the elder son was killed in France (1917) when serving with the Royal Engineers. By friends in all ranks of life, Scott will be remembered for many unrecorded acts of kindness as a botanist he has left a worthy memorial in his work and in the services he rendered to exact knowledge

A C SEWARD

DR. WILLIAM PAGE

WITH Dr. William Page, who died at Middleton in Sussex on February 3, at seventy-two years of age, has passed a singularly gracious personality, whose loss is regretted by a wide circle of friends. A far wider public will mourn, and continue to mourn, the editor of the most extensive and successful attempt ever initiated in Great Britain to produce a comprehensive series of county histories, a task to which Page devoted the last thirty-two years of his life

At the outset, indeed, a very different career had seemed to lie before Page. After leaving Westminster School, he became a civil engineer, and for a time (1880–84) was assistant executive engineer to the Government of Queensland But he already had other ambitions At the age of twenty-five he abandoned engineering, and with his brother-in-law, W. J Hardy, established a firm of record agents and legal antiquaries which achieved considerable distinction, and was engaged in a number of peerage, coronation and other claims During this period Hardy and Page jointly published the "Feet of Fines for London and Middlesex" (1892), and Page was incidentally able to develop that extensive and peculiar knowledge of local and customary history which was to serve him in good stead later In 1902 the Hardy-Page partnership was dissolved, and Page joined Mr H A Doubleday as joint-editor of the "Victoria County History", which had been established two or three years previously, whilst two years later, on the retirement of Mr Doubleday, Page became sole general editor.

The task which Page thereby undertook was immense alike in time and in space, including as it did the history, archæology, geology, botany and zoology of the English counties. Nor was it merely in breadth of knowledge and academic sympathy that the work demanded exceptional qualities in the editor The human problem—the problem of co-ordinating the work of innumerable specialists and local students, of harmonising their divergent views, abilities and eccentricities—drew incessantly upon Page's unfailing patience, courtesy and astuteness The contributions which he collected from these miscellaneous sources necessarily vary in value, but it is rarely that they fall below that high minimum of scholarship which he set himself to maintain On the documentary side, the editor's wide first-hand knowledge was a sufficient guarantee On the architectural side, Page's association with Sir Charles Peers resulted in the evolution of methods and standards which are likely to control all future research of the kind Indeed, these methods have received an enduring sanction in their adoption by the Historical Monuments Commission (England), which is in many ways the child of the "Victoria County History".

Nor did the editor's human problem end with his contributors. Financial difficulties were never far from Page's mind, and more than once the "History" seemed to be doomed to founder on this rock. But Page's untiring courage did not fail him, and on more than one occasion he was able to secure at the last moment the patronage which his work demanded In 1910 the generosity of the late Lord Hambledon carried the "History" forward a further stage, and in recent years, although financial support was increasingly difficult to obtain, individual guarantees facilitated the publication of volumes relating to Northamptonshire, Huntingdonshire, Rutland and Kent. In 1932 Page offered to the University of London, subject to certain conditions, the copyright and unused material—a considerable and important collection—of the "History", and the offer was gratefully accepted by the Court of the University in November of that year The Pilgrim Trust afterwards made a grant to the University of £500 a year for three years to assist in carrying on the work, and a University Committee associated with the Institute of Historical Research was established for the purpose It is indeed difficult to imagine that a task so well and truly begun, and already carried so far, should be allowed to lapse, and it is scarcely necessary to express the hope that, in accepting the legacy of Page's great work, the University has accepted the responsibility of completing it.

Page never courted any sort of recognition for his devoted work, but he was long a distinguished fellow of the Society of Antiquaries, of which he was a vice-president from 1916 until 1920, and in 1932 he received the degree of hon D Litt (Oxon)

WE regret to announce the following deaths

Baron Alphonse Berget, professor of physical oceanography in the Institut Océanographique, Paris, who published many works on physics and meteorology, on December 29, aged seventy-three years

Prof F. W Hardwick, emeritus professor of mining in the University of Sheffield, a past president of the Midland Institute of Mining, Civil and Mechanical Engineers, on January 24, aged seventy-three years

Prof T. E Peet, reader in Egyptology in the University of Oxford since 1933, formerly Brunner professor of Egyptology in the University of Liverpool, on February 22, aged fifty-two years

Sir Vincent Raven, K B E, president of the Institution of Mechanical Engineers in 1925, who published several works on electric locomotives and traction, on February 14, aged seventy-five years

Prof. Howard C Warren, professor of psychology in Princeton University since 1914 and editor of the *Psychological Review*, on January 4, aged sixty-six years

News and Views

Fundamental Cosmological Problems

PROF. M. N. SAHA, in his presidential address to the Indian Science Congress at Bombay delivered on January 2, dealt chiefly with fundamental cosmological problems. He believes that recent discoveries in nuclear physics will provide the key to the problems of stellar structure In the absence of decisive evidence, he inclines to the view of Kothari and others that the neutron should be regarded as a dipole consisting of a proton and an electron, and he believes that this structure has far-reaching astrophysical consequences. The problem of the ultimate fate of radiation has been radically transformed by the discovery of the positive electron, and the idea that final stagnation of the universe is inevitable is vitiated by the fact that it ignores the possibilities of conversion of radiation into matter and the combination of small into large energy quanta Prof. Saha considers that the experimental fact of "electro-fission of quantum", that is, the conversion of γ-ray quanta of sufficient energy into a pair of electrons, positive and negative, inside the nucleus, may prove to be the realisation, possibly on the cosmic scale, of the first possibility With regard to the second, he sees no theoretical reason why, in the radiation of space (presumably continuous from the hardest rays to visible light), hard cosmic rays may not be the result of fusion of softer quanta He expressed the view that continuous evolution is confined to portions of the universe such as the earth and solar system, the cosmic process as a whole being cyclic

Scientific Organisation in India

THE latter part of Prof. Saha's address was devoted to problems of scientific organisation. The present world is a single economic and cultural unit, and this fact should direct political and economic action. Practical problems can be solved only by the application of scientific principles, and a new educational scheme should be devised by a world's congress of foremost thinkers, with the object of training the coming generation to a proper appreciation of the beauty and powers of science The lack of scientific organisation and preliminary research is particularly obvious in Indian public works, with serious consequences to the vitality of the population and resulting in great waste of money Prof Saha supported the formation of an Indian Academy of Science, organised somewhat on the lines of the Royal Society, which would co-ordinate Indian scientific work, and act generally for the promotion of scientific research and its utilisation in national and international affairs He adduced evidence of the need of such a body, quoting in support of his view the statement of Sir F. Spring on river problems in India, that "more money has been wasted, for want of just such knowledge as a River Commission might provide, than would have sufficed to pay the entire cost of it many times over".

Dinosaur Skeletons in Brussels

WE regret to learn that the remarkable skeletons of the Wealden Dinosaur Iguanodon, which form the most striking feature of the Royal Museum of

Natural History in Brussels, are beginning to decay. The bones are unfortunately much pyritised, and being exposed to moist air, the pyrites becomes oxidised and causes disintegration. The director of the Museum, Dr. Victor Van Straelen, has for some time arranged to treat the more fragile parts with preservatives, but he realises that the only method of permanent preservation is to enclose the specimens in glass cases in which the air can be kept dry. He has accordingly induced the Belgian Government to ask Parliament for a sum of money sufficient to provide the cases. The Belgian Senate, however, after an animated discussion, has refused the appropriation on the ground that the preservation of these fossils is not worth the needed expenditure. To this Dr. Van Straelen has fittingly replied, that if the Belgian nation is unwilling to preserve so great a scientific treasure, the skeletons of Iguanodon should be offered for sale to museums in other countries, which would be glad to acquire them and keep them intact for research. Palæontologists everywhere will certainly endorse this proposition. The Belgian Senate, years ago, provided a large sum of money to obtain the unique collection of Iguanodons and other important fossils from the mine of Bernissart, to the great benefit of science and the enlightenment of the Belgian people. It is to be hoped that the Senate may yet reconsider its present retrograde step.

Ultra-Short Wave Radio Links for Telephony

It is now well known that electric waves having a wave length of less than about 8 metres are of little use for long-distance radio communication, owing to the apparent inability of the ionosphere to deflect such waves back to the earth's surface. For shorter distances and particularly over stretches of water, however, these short waves are being found to have a useful application in providing a radio link in the ordinary land line telephone system. In this connexion, the radio link is an alternative to the use of a submarine cable, and it has the advantages of lower installation cost and ease of maintenance. An experimental two-way circuit of this type, operating on a wave-length of about five metres, was inaugurated by the Post Office engineers across the Bristol Channel in 1932 (see NATURE, 130, 604, Oct. 22, 1932). This radio circuit operates between Cardiff and Weston-super-Mare and links up with the ordinary inland telephone network, thus forming part of the London-Cardiff trunk circuit. The recent opening of a similar radio link, on a much shorter wave-length, across the English Channel for use in connexion with the cross-channel air services was referred to in NATURE of February 3, p. 167.

According to a report in the *Times* of February 24, the Postmaster-General, in his address to the Lincoln Chamber of Commerce, referred to the probable extension by the Post Office of the facilities provided in the radio link across the Bristol Channel. Modern submarine cables usually contain many circuits so that several conversations are possible simultaneously; and a similar facility must be provided by the radio link if this is to compete successfully with the cable. The experimental work which is now being conducted by the Post Office is directed towards ascertaining the practical possibilities of operating, between two fixed points, several small radio transmitters each on a separate wave-length and carrying a single conversation. The necessary equipment for this practical test is now being installed at Castleton, Monmouthshire, and at Backwell Hill, near Bristol. There will be six transmitters and six receivers on each site, and each of these will be associated with its own directional aerial system. All the twelve wave-lengths to be used will be within the range four to six metres. The whole system is being designed for economical operation, and such devices as the automatic charging of batteries and the indication at the controlling telephone exchange of faults on the radio link, are being incorporated. It is hoped to begin the tests in two or three months' time and the results of this larger-scale practical trial will be awaited with interest.

Structure of Chlorophyll A

The fourth Pedler Lecture of the Chemical Society was delivered by Prof. Hans Fischer at the Royal Institution on February 22, his subject being the constitution of chlorophyll A. Prof. Fischer has been working on blood and leaf pigments in Munich for a number of years, and has recently synthesised hæmin, which is obtained from blood by heating with acetic acid and sodium chloride. He was awarded the Nobel prize for chemistry for 1930. The lecturer dealt first with the porphyrins, a group of compounds upon which both hæmin and chlorophyll are based, and which all contain a ring of four pyrrole-like nuclei. Willstätter's work has shown that substances of this type are formed in the breaking down of chlorophyll, but now many of these complex molecules have been synthesised, and the nucleus of chlorophyll is known with certainty to be an isomeric modification of the porphyrin ring. The hæmin molecule has essentially the same nucleus, but different side chains. It contains two vinyl groups, which are hydrogenated to ethyl groups in chlorophyll. The latter also contains an additional ring structure, derived from β-keto propionic-acid, in place of the propionic acid side chain of the hæmin molecule. In chlorophyll, a magnesium atom replaces the co-ordinately bound iron atom of hæmoglobin. The final formulation of the structure of the chlorophyll molecule has entailed an enormous amount of synthetic organic chemistry of the utmost complexity. The brilliant manner in which Prof. Fischer and his co-workers have carried it out makes one confident that they will ultimately succeed in the synthesis of chlorophyll itself.

Bootham School Natural History Society

The foundation of this School Natural History Society in 1834 was an important landmark in educational history, and a largely attended meeting at Bootham School, York, celebrated its centenary. An interesting exhibition of work done by past and present members gave striking evidence of the range of interest and the far-flung activities of Bootham Old Boys. The headmaster read messages of greeting from the Minister of Education, Sir Michael Sadler and many others. Referring to distinguished former members such as Joseph Barcroft, F. W. Oliver, S. P. Thompson, J. Gilbert Baker, Lewis Richardson, Sir George Newman and Henry Seebohm, he claimed that the Society has performed, through the lives of its members, great services to the development of tropical countries, as well as to pure science. Above all, it has given to a great number of men a permanent enrichment of life. Mr. J. L. Paton, formerly High Master of Manchester Grammar School, gave an inspiring address. He warmly commended the pioneering step taken a hundred years ago in bringing biological science into the school. He spoke of those naturalists overseas as conquerors, not of men, but of Nature. Finally, he maintained that men do not really know Nature until they know her as the interpreter or the medium of the supernatural.

The Diesel-Electric Train Ferry *Scilla*

FOR nearly forty years a service of train ferries connecting Sicily with the mainland has been running across the Strait of Messina. The distance between the two terminal points, Messina and Villa San Giovanni, is about five miles. Until recently the service was maintained by two small ships which crossed in opposite directions simultaneously, so as to prevent an accumulation of rolling stock on either side of the Strait. In October 1931 they were replaced by the Diesel-electric train ferry *Scilla*, which has a displacement of 4,000 tons and a length of 358 ft. In *Engineering* of February 23, a full description is given of the vessel. It has a horse power of 5,000 and a maximum speed of 17 miles per hour. The coaches are embarked and disembarked at the end by means of a movable bridge. The adoption of Diesel electric propulsion for a vessel of this type has several advantages, in particular its ability to run economically at different speeds, and rapid and accurate manœuvring. There are two steering stations on the vessel, one on the boat deck and the other in the engine-room, and interlocks are provided so that it is impossible to operate the controls from both stations at the same time. The ferry carries both passengers and goods, and traffic in the latter and more particularly the transport of fruit, has steadily increased since its inauguration. It is of a seasonal nature with a winter maximum, a summer minimum and a short peak load in June. The crossing takes 25 minutes and there are first and second class restaurants on the passenger deck. The corridor deck contains first, second and third class saloons for the passengers.

A James Watt Letter

A MOST interesting letter written by James Watt in 1784 to his father-in-law, Mr. Macgregor, has just been presented to the University of Glasgow by Mr. W. J. Wilson. The letter was published in full in the *Glasgow Herald* of February 9. Watt had once made surveys for the Caledonian Canal, and it had been proposed that he should become the engineer of the scheme. By 1784, however, he had become so fully occupied with the engine business at Birmingham that he felt he could not accept the position. He said, "the contriving of engines and the other necessary attention to a business which is now very extensive takes up all the time that bad health will permit me to work, and it is possible that, setting aside the damage which the distraction of my attention might do to the partnership, my share of the loss in the engine business might exceed my gain by the canal direction." Speaking of his great contemporary Arkwright, Watt said, "he is to say no worse one of the most self sufficient ignorant men I have ever met with. Yet by all I can learn he is certainly a man of merit in his way and one to whom Britain is much indebted and whom she should honour and reward, for whoever invented spinning Arkwright certainly had the merit of performing the most difficult part, which was the making of it usefull." When Watt wrote this letter he was forty-eight years of age, and eight years previously had married his second wife, Anne Macgregor.

Institution of Mechanical Engineers

AT the annual general meeting of the Institution of Mechanical Engineers held on February 16, the annual report was adopted and the ballot for the election of officers declared, Mr. C. Day becoming president for the ensuing year in succession to Mr. A. E. L. Chorlton. Honorary life membership, it was announced, had been conferred upon Mr. L. St. L. Pendred and the Right Hon. Lord Invernairn. The report showed a net increase in the roll of membership of 61 names, the total number of members now being 11,356. The total revenue of the Institution was £34,074. During the year the meeting hall had been much improved and the library accommodation increased. A standing Committee, entitled the Inventions Advisory Committee, had been formed to assist members, while another committee, entitled Works of National Importance Committee, had been established to consider proposals for works of national importance which could be submitted to the Government for consideration with the view of lessening unemployment. The report contains short reviews of the work done by the various research committees, the awards for papers and the results of the examinations for National Certificates and Diplomas in Mechanical Engineering. For these examinations there were 2,989 candidates in England and Wales, 226 in Scotland and 37 in Northern Ireland, a greater number than in any previous year. Twenty National Diplomas (Air) in Mechanical Engineering were awarded jointly by the Institution, the Board of Education and the Air Ministry.

Streets and Pavements in London

IN a paper read to the Newcomen Society on February 21, an interesting sketch was given of the history of the streets and pavements of London. In only two periods in its long history has London been efficiently paved and drained: in the days of the Romans and during the last hundred years. How well the Romans worked can be seen from the remains of causeways and sewers now and again brought to light during excavations in the City. With the departure of the Romans went the art of road-making, and for century after century the citizens accepted with extraordinary complacency conditions which would not be tolerated in any city to-day. As a rule, the roads were unfit for wheeled traffic, the sidewalks were of gravel and dirt, the rain spouts projected over the pavements and such sewers as there were were connected ineffectively with gutters full of holes. Complaints were made over and over again, and though surveyors and paviors were appointed, things were seldom satisfactory. Even in the days of Wren and Newton, Ludgate Hill and Fleet Street drained into the mud-filled Fleet River, which had long ceased to be navigable and had become a nuisance. Westminster was every bit as bad as London, and in 1742 Lord Tyrconnel in the House of Lords said: "The filth of some parts of Westminster and the inequality and ruggedness of others, cannot but in the eyes of the foreigners disgrace our nation, and incline them to imagine us a people, not only without delicacy, but without government, a herd of barbarians, or a colony of hottentots." Improvements were effected from time to time, it is true, but it was only during last century that real progress was made.

Archæological Exhibitions at the British Museum

At the recent annual meeting of the subscribers to the British School of Archæology in Athens, reference was made in the usual review of the School's work to the votive house, or temple, models which had been discovered in the course of the excavation of the Heræum at Perachora, near Corinth. From incomplete fragments a complete model has been reconstructed, which is now on view in the British Museum. The model is about a foot in height, and gives for the first time an idea in detail of the character of the house in the Ægean during the Geometric period. The models are dated at about the middle of the eighth century B.C. The most striking feature of the construction is the apse, which Sir Arthur Evans has suggested may have arisen from the earliest form of building, in which the back wall was formed by hollowing out a cliff face. The door of the building has antæ with columns, and above it are three small windows.

On March 7 an exhibition will open of the finds of the joint expedition of the British Museum and the British School of Archæology in Iraq under the leadership of Mr. M. E. L. Mallowan, at Arpachiyah, near Nineveh, in northern Iraq, during the season 1932–33. This material should have been on view last summer, but its dispatch from Iraq was delayed by action of the Government in settling the allocation of the material found by the expedition. The finds now shown will illustrate the cultures of the ten successive prehistoric settlements discovered at Arpachiyah. This sequence, in which the occurrence and development of the painted pottery can be followed from the earliest settlement, and the evidence of early relations with prehistoric India, Baluchistan, southern Mesopotamia and Crete, make Arpachiyah one of the most important sites known for the early prehistory of Iraq. Unfortunately, partly owing to lack of funds, excavations have been suspended.

Recent Acquisitions at the Natural History Museum

By the will of the late Lieut.-Col. C. G. Nurse, the Trustees of the British Museum (Natural History) have received a bequest of 3,000 Indian insects mostly obtained at Quetta, Deesa and Jubbulpore, where Col. Nurse served with the Indian Army. Col. Nurse was one of the small band of naturalists among military officers who devoted their leisure to the study of entomology, and was an enthusiastic collector of Hymenoptera, forming a large and valuable collection which he presented to the Museum a few years ago. The present bequest comprises the remainder of his Indian insects and includes about 1,450 Diptera (two-winged flies), 1,300 butterflies, 130 dragon flies and some others; of these the most valuable are the Diptera. The collection is especially rich in species of the family Bombyliidæ, most of which are parasitic in the larval state on bees or wasps. Col. Nurse discovered and described fourteen species of this family which were new to science, and types of these are in the collection, as well as specimens of a number of other flies which were not previously represented in the Museum. Some interesting butterflies and other insects from Aden are included.

The Department of Botany of the Museum has been presented with sixty-three bundles of plants by the Hancock Museum, Newcastle-upon-Tyne. These plants were presumably presented to the Newcastle Museum by William Robertson, who bought them at the sale in 1842 of A. B. Lambert's herbarium, which was one of the largest ever in private hands. The specimens are of historical interest as they presumably include the remainder of the herbarium of P. S. Pallas, a Russian botanist who died in 1811. Pallas's plants were acquired by Lambert, who picked out one set for himself and one for Sir Joseph Banks. Banks's set went to the Museum in 1827, and Robert Brown purchased Lambert's own set at the sale. Judging from the specimens so far examined, the present acquisition represents the remainder of the herbarium. Much will probably be duplicate material but a good deal of information can be obtained from the original wrappers in which the plants still are. Further, it is probable that some plants figured by Pallas, which have been missing, will be brought to light. The bundles also contain about 500 plants collected by the Rev. E. D. Clarke, who visited Pallas in the Crimea in 1800. The plants were named by Pallas. Among the purchases are 800 flowering plants from Spain and Morocco (Sennen), 1,500 from North America (Marcus E. Jones) and 900 from Eastern Greece, Ægean Islands, etc. (K. H. Rechinger).

Good Eggs and Old Age

THE man or woman who lives to be eighty years old started as an "extraordinarily good egg" is a conclusion stated by Dr. George L. Streeter, director of the Department of Embryology of the Carnegie Institution of Washington, according to Science Service, Washington Human eggs, like hen's eggs, vary greatly in nature and quality It is estimated that one fourth of the fertilised human ova are not good enough eggs to be born as living individuals Whether the infant survives its first year – and, in fact, a large number of them fail to do this—depends in considerable part on the original quality of the egg The individual who withstands the usual experiences of life until between fifty and sixty years old and then succumbs to its aggregate wear and tear, conforms to the actuary's 'expectation of life at birth' and to the embryologist's expectation of the performance of an egg of average quality It is only the extraordinarily good egg that is still going strong at eighty years, and we see him or her doing this in the absence of any exquisite hygienic regime or environmental favour

Plant Collecting in Persia

THE *Gardeners' Chronicle* is always to the fore in publishing reports of expeditions organised for the collection of new plants In the issue of January 6 appeared the first of a new series of articles on "Plant Collecting in Persia" by Mr. E K Balls The account gives full descriptions of the habitats of a wide variety of plants, particularly irises, campanulas, gentians and *Dionysia* More intimate details of the trip are also included The second article appeared in the issue of January 20, and articles are promised for some time ahead If the plants collected prove amenable to cultivation in Great Britain, many beautiful species will be placed at the disposal of gardeners

International Union for Chemistry

THE eleventh conference of the International Union for Chemistry will be held at Madrid at the same time as the ninth International Congress of Pure and Applied Chemistry Among the matters to be considered by the various commissions of the Union are the reforms of inorganic, organic and biochemical nomenclature, physico-chemical standards; co ordination of scientific terminology; international tables of constants; and finance The election of president and vice-presidents, and the nomination of members of commissions, will take place on April 11

International Congress of Actuaries

THE Tenth International Congress of Actuaries will be held at Rome on May 4–10 The subjects for discussion will cover a large field and particular attention is being given to different aspects of social insurance, including unemployment insurance Various social functions and excursions have been arranged and the Congress promises to be one of the most interesting of recent years The British Government has appointed as its representative the Deputy Government Actuary, Mr. G. S. W. Epps. It is hoped that those Cabinet Ministers whose Departments are specially concerned with actuarial questions will be associated in an honorary capacity with this as with past congresses Membership of the Congress is open to members of the Permanent Committee of International Congresses of Actuaries and, subject to approval by the Managing Committee, to others or institutions professionally associated with actuarial work. Further information can be obtained from Mr Geoffrey Marks, C B E, 39, King Street, E C 2, or Mr. Stuart Cumming, 19, St. Andrew Square, Edinburgh

International Agricultural Congress

THE third Technical and Chemical International Congress of Agricultural Industries will be held in Paris on March 26–31 The Congress will be followed by a tour of the French wine-growing districts, arranged so that those delegates who wish can continue to Madrid in time for the opening of the ninth International Congress of Pure and Applied Chemistry on April 5 The work of the Congress is divided into five main sections scientific and economic studies, sugar manufacture, fermentation industries, food industries, and allied industries The subjects selected for discussion cover a wide range, but will be chiefly of interest to technologists in the sugar and fermentation industries. Other questions to be discussed include water pollution, and new uses for surplus agricultural produce, in Section 1, the properties of wheat and flour in relation to bread quality, and the treatment of milk from the farm to the consumer, in Section 4, the use of alcohol fuels and of vegetable oils in motors, in Section 5 These ensure that the Congress will appeal to a wide circle of agricultural and other technologists Adequate arrangements have been made for relaxation from the more serious work of the Congress The subscription for individual delegates is 100 francs, payable to the Treasurer, M Combrun, 156 Boulevard de Magenta, Paris, from whom application forms and other details may be obtained

The Seventh Achema

WE have received an illustrated leaflet which contains the preliminary announcement of the seventh 'Achema' or Exhibition of Chemical Plant and Apparatus, organised by the 'Dechema' (Deutsche Gesellschaft für chemische Apparatewesen), which will be held at Cologne during Whitsuntide (May 18–27). The event has been timed to coincide with the annual meetings in the same city of several of the leading German allied societies, and the exhibition will be held in three large buildings on the banks of the Rhine and within easy walking distance from the centre of the city. Four years will have elapsed since the sixth 'Achema' was held at Frankfort and the promoters confidently claim that this will be the greatest exhibition of its kind that has yet been held anywhere in the world. Most of the leading German firms who supply chemical plant and apparatus have already booked stands and a big gathering of experts is expected A graph on the pamphlet shows how rapid has been the growth in popularity of this undertaking since the first 'Achema' was held at Hannover in 1920 Admission cards will be issued free on application to the Management, Dechema Gesellschaftsstelle, Seelze bei Hannover. Two international postage stamps should be enclosed A handbook containing fuller particulars will be issued shortly Arrangements are being made by Messrs Hagemann and Co, Travel-bureau, Bad Aachen, Bahnhofstrasse, 32, for the issue of cheap excursion fares from England and other countries

Universal Decimal Classification in Germany

THE past three years have witnessed in Germany a rapid development of interest in the universal decimal classification, the most important manifestation of which has been the adoption of that system by the Deutscher Normenausschuss for codifying its published standards The need for a German edition of the classification has been felt, and is now to be met The production of a new (third) edition of the classification will take place in the next three years, 1934–36, under the auspices of the Normenausschuss and the Ministry of the Interior The work has the official approval of the Institut International de Documentation and will incorporate all the considerable amendments and additions made to the second French edition 1927–29 since publication of the latter The additions will total some 10,000 classes, mainly in science and technology, bringing the total number of classes to approximately 70,000 The work will be published in ten quarterly parts, of standard format *A* 4 and comprising about 160 pages The first part will appear in April of this year, and the cost of each part will be 11 gold marks if ordered before March 1, afterwards 12 50 gold marks Messrs Beuth-Verlag, G M B H, Berlin, S W 19, are the publishers.

The Night-Sky in March

THE only striking planetary object in the March sky is Jupiter, which can be seen in the eastern sky before midnight close to the star α Virginis (Spica), and the two form a conspicuous pair There will be an occultation by the moon of the star α Scorpii (Antares) on March 8, but the phenomenon will not be visible at Greenwich (it will be visible at the Cape of Good Hope) On March 26 the moon will occult δ Cancri, the magnitude of which is 4 2 This occultation will be visible at Greenwich and will take place early in the morning (at 3h 02m G M T) At this hour the phenomenon will scarcely tempt any save regular observers of occultations, especially as we can warn our readers of two occultations which will occur later in the year of bright stars both of which will occur before midnight.

Announcements

THE newly formed Microchemical Club will hold its first scientific meeting on Saturday, March 17, at 10.30 a.m. at the Lister Institute, Chelsea Bridge Road, London. At 2 30 p m on the same day and at the same place, the first annual general meeting will be held to elect officers, adopt a constitution and transact other business Communications on microchemical subjects are invited, they may deal with applications and development of micro methods in any branch of science Communications can be sent to S J Folley, National Institute for Research in Dairying, Shinfield, Nr Reading

THE prize for 1933 of £100 awarded by the Thomas Gray Memorial Trust of the Royal Society of Arts for an essay in connexion with fire in a modern passenger vessel or in a cargo vessel at sea, in port or in a builder's yard has been awarded to Commander R D Binney The prize of £100 for an improvement in the science or practice of navigation has been awarded to Dr A B Wood, F D Smith and J A. McGeachy, Admiralty Research Laboratory, Teddington, for their silent magneto-striction echo sounder with recorder The prizes for 1934 are being offered for an invention, publication, diagram, etc, which is considered to be an advancement in the science or practice of navigation and for an essay on a navigation topic Essays or proofs of claim must be submitted before December 31 Titles of the essay and other information can be obtained from the Secretary, Royal Society of Arts, John Street, Adelphi, London, W C 2

IN an article on "Industrial Research" in NATURE of January 20, it is stated on p 80 that the contribution of electric supply authorities in Great Britain to the British Electrical and Allied Industries Research Association is about £5,000 We are informed by the Association that its income from this source in 1933 was £15,000

APPLICATIONS are invited for the following appointments, on or before the dates mentioned.—A probationary assistant engineer (male) in the Post Office Engineering Department—The Secretary, Civil Service Commission, Burlington Gardens, London, W 1 (March 8) A senior library assistant to the Hertfordshire County Council—The Clerk to the County Council, 28, Castle Street, Hertford (March 10) A head of the Mechanical and Civil Engineering Department of the Technical College, Sunderland—Chief Education Officer, Education Offices, 15, John Street, Sunderland (March 12) A University professor of anatomy at St Thomas's Hospital Medical School—The Academic Registrar, University of London, S.W 7 (May 16) A director of food investigation in the Department of Scientific and Industrial Research—The Secretary, 16, Old Queen Street, Westminster, S W 1 (March 17) A head mistress of the Day Trade School for Girls, Wavertree Technical Institute—The Director of Education, 14, Sir Thomas Street, Liverpool (March 17) A professor of mathematics at the Royal Technical College, Glasgow—The Secretary (March 26) A staff lecturer and demonstrator in botany, and a demonstrator and assistant lecturer in chemistry at the Royal Holloway College, Englefield Green, Surrey—The Principal (April 14). A signal engineer for the Way and Works Department, Government Railway, Ceylon—Crown Agents for the Colonies, 4, Millbank, London, S.W.1.

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

A supposed Submarine Ridge along the South-East Coast of Greenland

DURING marine biological work in the Denmark Strait with the Danish Research Ship *Dana* in August 1933, it was possible to proceed quite close to the coast of East Greenland south of Angmagssalik; practically no ice was met with during this year. For the purpose of the biological work on the drift of cod larvæ from Iceland to Greenland with the west-going branch of the Irminger Current, four sections were made from the coast out to deep water. During these sections, as also on the whole cruise, the echo sounding apparatus was constantly used and the soundings revealed—so far as it was possible to carry out the investigations during the time available—that a submarine ridge seems to follow the East Greenland coast, at any rate from about Lat. 64° N. to Cape Farewell (lat. 60° N.).

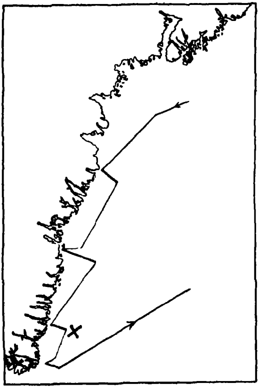

FIG. 1. Course of the *Dana* off the south-east coast of Greenland.

Our work during the cruise was, as mentioned above, mainly marine biology, and it was impossible to go further into the studies of the relief of the sea bottom last summer. The matter is, however, of importance in several respects, and I wish therefore to announce our observation of this supposed ridge that other ships may possibly have the opportunity of making further soundings there and thus eventually prove or disprove the existence of this supposed submarine ridge in these remote waters. Our soundings point to a continuous ridge, but more close investigations are however necessary, as breaks may possibly be found in the ridge off the deeper fjords.

In Fig. 1 is given a rough sketch of the coast of East Greenland south of Angmagssalik showing the route of the *Dana*. Fig. 2 shows the bottom relief on one of the sections (marked with a cross in Fig. 1); the other sections show, however, on the whole, much the same conditions. It will be seen that the submarine ridge is about 230 metres below the surface in the section in Fig. 2 and it is about 20 miles off the coast line. Farther north the ridge is more than 20 miles from the coast-line (going up to about 30 miles). The greatest depth measured inside the ridge where the depths are rather variable is about 600 metres; outside the ridge the depth increases very rapidly to more than 1,500 metres. On the ridge itself we obtained depths of 170–240 metres, most often 200–240 metres. In the trough formed by the ridge along the coast we have the ice-cold East Greenland Current; outside or over the ridge we met with the warm Atlantic water with temperatures up to 8° C.; between these water masses we have mixed water layers.

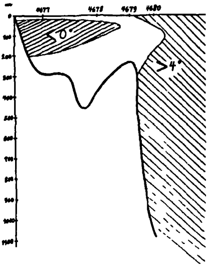

FIG. 2. Section at X in Fig. 1, showing submarine ridge and temperature of the bodies of water on each side of it.

During recent years the late Prof. Johs. Schmidt succeeded in showing that there is an interchange of the stock of cod in Icelandic and Greenlandic waters. In 1933 the migrations of cod from West Greenland to Iceland were even greater than in preceding years in which investigations were undertaken. Probably it will be possible in the future to show that the cod migrating from one of the areas mentioned to the other follow the ridge in question, where 'cod temperatures' will probably prevail during most years. We shall then be able to understand how the cod find the path from West Greenland to Iceland and vice versa.

Constitution of Dysprosium, Holmium, Erbium, Thulium, Ytterbium and Lutecium

CONTINUING the examination of the rare earth elements by the method of anode rays as already reported[1], I have now been able to complete the analyses of the group

Dysprosium (66) gave poor spectra but sufficient to indicate that it consists of mass numbers 161, 162, 163, 164 not differing much in relative abundance.

Holmium (67) is quite definitely simple 165

Erbium is not so complex as it was at first supposed to be. The early samples used were evidently contaminated A pure sample gave three strong lines, 166, 167, 168 and a weak fourth 170

Thulium (69) is simple 169

Ytterbium (70) appears to contain mass numbers 171, 172, 173, 174, 176, of which 174 is the strongest

Lutecium (71) is simple 175

It will be seen that these six elements fill all the numbers from 161 to 176 and show no isobares.

A full account of this work will be published in due course with estimates of relative abundance and the atomic weights so deduced It is already evident that the international values for several of the rare earths are in need of revision That of holmium (163 5) is particularly bad

Value of e/m

SIR ARTHUR EDDINGTON[1] has developed theories according to which

$$hc/2\pi e^2 = 137,$$

and the ratio of the mass of the proton to that of the electron is

$$M/m = 1847\ 6$$

I have shown[2] that these theories and most experimental data are in extremely good mutual agreement The only experimental evidence against them[3] is that given by recent determinations of the specific electronic charge[4], which may be summarised as

$$e/m = (1{\cdot}759 \pm 0\ 000_5) \times 10^7 \text{ E.M U.}$$

These measurements disagree with the value deduced[5] from $M/m = 1847\ 6$, namely,

$$e/m = (1\ 77031 \pm 0\ 00014) \times 10^7.$$

However, Sir Arthur Eddington pointed out[6] that his work and the discovery of the neutron made it seem likely that the equations used in deducing the spectroscopic estimates of e/m are in error.

I am writing to suggest that some (or possibly all) of the experimental determinations of e/m are really measurements of

$$\frac{136}{137}(1{\cdot}77031 \pm 0{\cdot}00014) \times 10^7;$$

that is to say, of $(1{\cdot}757{,}4 \pm 0{\cdot}000{,}14) \times 10^7$ E M U. This is in reasonable accord with the $1\ 759 \pm 0\ 000_5$ recently obtained experimentally (being smaller than some and larger than other of the experimental results)

If this supposition proves to be correct, the only evidence against Sir Arthur's 137 and 1847 6 would vanish.

Reaction of Heavy Water with Metallic Sodium

MESSRS C O DAVIS and H L Johnston report[1] that when metallic sodium is dissolved in heavy water, the diplogen content of the evolved hydrogen is reduced and the diplogen content of the solution correspondingly increased We wish to put forward the results of similar experiments, which have been carried out in a somewhat different way and seem to lead to a more precise interpretation of this reaction.

Metallic sodium was introduced into an evacuated glass bulb by electrolysis, and heavy water was then distilled into the vessel In two experiments an excess of water was taken, in two other runs there was an excess of sodium metal. In all experiments the quantity of hydrogen evolved was found to be 0 5 mol. per mol of decomposed water. The original water contained 1·81 parts of diplogen to 100 parts of hydrogen + diplogen

1. Water excess, room temp.	0 96	per cent D in H_2+HD formed
2. Sodium ,, ,,	0 99	
3 ,, ,, $-10°$ C	1 01	
4. Water excess, room temp.	1 03	

These values are in agreement with the 'separation factor' reported by Davis and Johnston

Since in presence of an excess of sodium the whole of the water was decomposed, the shift in the diplogen content of the hydrogen produced cannot be accounted for by a difference in the rate of reaction of H_2O and HDO with sodium. The case is therefore different from the shift observed in the reaction between iron and water[2]

The correct description of the phenomenon appears to be this · Decomposition of HDO by metallic sodium can lead alternatively to the formation of NaOH or NaOD, the latter alternative being preferred Or, putting it in a different way: when HDO comes into contact with sodium, the H-atom escapes with greater ease to combine with an H-atom released by a neighbouring pair of reacting particles ($Na+H_2O$), than does the D atom.

The greater ease of reaction of H as compared with D was predicted by Cremer and Polanyi[3] on account of: (1) the lower zero point energy of D-compounds[4], (2) the stronger leakage of H through energy barriers

In the present case of a single compound entering into two alternative reactions, the zero point energies of the initial states are identical. However, at the top of the activation barrier the two alternative reactions will show a difference in energy due to the different zero point energies of NaOD and NaOH. The former having the smaller zero point energy, the barrier will be lower, when NaOD is formed Formation of NaOD would therefore be preferred. An estimate of the effect of zero point energy makes it possible to assume that this is sufficient to account for the ratio of the two reaction rates actually found

Obviously the difference in the 'leakage' of the particles H and D would also lead to a preference of the observed reaction

We wish to express our thanks to Prof Polanyi for valuable discussions.

Production of Induced Radioactivity by High Velocity Protons

CURIE and Joliot[1] have reported that a number of new radioactive isotopes can be produced by the bombardment of various elements with α particles, these isotopes emitting positive electrons In particular, they showed that boron when bombarded by α-particles was transformed to the isotope N^{13}, radio-nitrogen, this isotope having a half life of 14 minutes They suggested that the isotope might be produced by the bombardment of carbon with heavy hydrogen, the product, N^{14}, disintegrating with the emission of a neutron to radio-nitrogen

We have bombarded a target of Acheson graphite with *protons* of 600 k v. energy and have used a Geiger counter to search for any radiations produced after the bombardment ceased After bombardment for 15 minutes with a current of about 10 microamperes of protons, the target was removed from the apparatus and placed against the Geiger counter We then observed about 200 counts per minute, being about forty times the natural effect The number of counts decayed exponentially with time, having a half life of $10\ 5 \pm 0\ 5$ minutes

We then carried out an experiment similar to that performed by Becquerel, in which the source was placed on one side of a 9 mm thick lead plate with the counter on the opposite side, the whole being placed in a magnetic field, so that any electron emitted could only reach the counter by applying a field of appropriate sign and magnitude We found that when the field was such that positive electrons could reach the counter, the number of counts increased by a factor of 3, when the field was in the reverse direction no definite increase was observed We conclude, therefore, that the radiations consist in part at least of positive particles

We have also taken about 250 Wilson chamber photographs in a field of 2,000 gauss, placing the activated source against the outside of the chamber wall, which was about 3 mm. thick Under these conditions, we observed only two electrons of positive curvature which could possibly have come from the source, these electrons having energies of the order of 500 k v We observed, on the other hand, 48 tracks of Compton electrons starting in the gas, having energies ranging from 100 k v to 500 k v., suggesting the emission of γ-rays of energy between 500 k.v and 1 million volts These γ-rays may result from the annihilation of the positive electrons, presumably in the glass wall of the chamber The deflection experiments, whilst not at present precise, tend to confirm that few of the positive electrons would have sufficient energy to penetrate the glass walls Further experiments will, therefore, be carried out with the source inside the chamber *

The observations suggest that the unstable isotope N^{13} is produced by the addition of a proton to C^{12} The difference between the half life observed and that reported by Curie and Joliot may be due to the formation of N^{13} in a different excited state

No marked increase in the number of counts was observed when a mixed beam of heavy hydrogen ions and protons was substituted for the proton beam

We are very much indebted to Dr K T Bainbridge, who supplied the Geiger counter with which the observations were made

A Perturbation in the Spectrum of Se II

WHEN the analysis of the spectrum of Se II has been completed, it is observed that the quartet

$$\begin{aligned} & & & \nu\ (\text{int}) \\ 4p\ {}^4S_{1\,1/2} & - 5s\ {}^4P_{1/2} & = & \ 95270\ (10) \\ & - 5s\ {}^4P_{1\,1/2} & - & \ 96753\ (10) \\ & - 5s\ {}^4P_{2\,1/2} & - & \ 98676\ \ (4) \end{aligned}$$

due to the fundamental transition $4p \rightarrow 5s$ exhibits abnormal relative intensities of its components The intensity ratio of these lines, according to Burger and Dorgelo's rule, should be 2 4 6, the line $S_{1\,1/2}-P_{2\,1/2}$ being thus the brightest and the most easily excitable of the group, whereas in Se II, it is extremely faint under all the variety of experimental conditions of excitation in which the group has been photographed The corresponding quartets in other similar spectra, hitherto known, do not show this anomalous feature.

In Se II this must obviously be a perturbation in intensity arising from the mutual interaction of adjacent spectral terms ; for our analysis has revealed a clear interpenetration of the levels due to the *5s* and *4d* configurations, while in the lighter elements there is a somewhat large separation between these two groups of energy states

Excepting this intensity anomaly, the other characteristics of Se II are found to be generally analogous to those of As I or S II. Full details of this scheme will be published shortly.

Feeding Mechanism of the Fairy Shrimp

In a recent paper[1] Mr. Lowndes has put forward a new view as to the filtratory feeding mechanism of the fairy shrimp, *Chirocephalus diaphanus*. Hitherto all workers (Storch[2], Lundblad[3], Naumann[4], Borradaile[5], Wagler[6] and Cannon[7]) have agreed that the long setæ on the edges of the basal endites of the trunk limbs constitute the filter, or at least a retaining wall by which particles are abstracted from a current of water.

Mr. Lowndes maintains that water enters the inter-limb spaces between successive limbs, past the endopodites and exite series, which hitherto have been accepted as valves preventing the inflow of water, and that some of this water is then forced into the deep food groove running along the mid-ventral line of the body. Here it is filtered by patches of setules on the food groove walls, which he calls the "filter processes".

In a recent paper[8] I described and figured these 'filter processes' in the three orders of Branchiopoda in which they occur, and showed that they are comb setules which comb the residue off the filter setæ on the basal endites. That the latter are actually filters is shown by the two facts: (1) the water current can be seen to pass through them from the mid-ventral space, as I described in 1928, and (2) they have the typical structure of filter setæ. In all those numerous forms where, either experimentally or by the position of the food in sections of the fixed animal, it can be shown that a limb acts as a filter, the same type of seta is found (Cannon[8], p. 275) and this is the type found in *Chirocephalus*.

In all filtratory setæ the ultimate meshes of the filter are formed by fine setules regularly arranged on the edges of the setæ. If further evidence is required beyond direct observations that the water current passes from the mid-ventral space through the filters, it is found in the position of its setules – they always face the direction from which water to be filtered comes, and in *Chirocephalus* they all face the median plane.

The only point previously on which workers have been unable to agree is as to the mechanism by which the filtered food is transported to the mouth. Storch[2] (p. 387) maintains that it is swept forwards by the action of the most proximal setæ on the basal endites, while I maintained[7] (p. 811) that there is a definite oral current in the food groove. This is the only current which cannot be observed directly, and so I demonstrated it experimentally. I injected a coloured solution so as to fill completely one of the inter-limb spaces of a captive *Chirocephalus*, and was then able to show that at the end of the backstroke of the limb forming the anterior wall of this space, a spurt of the solution was forced along the food groove. Mr. Lowndes has now repeated my experiment and confirmed my results.

'Mimicry' among Insects

There has just come to hand (*Entomologica Americana*, 13, No. 3, published (as stated on cover) Nov. 29, 1933, but dated on every page December 1932) a most admirable review of the Polybiine wasps of the Nearctic region, by Dr. J. Bequaert. Unlike many taxonomic papers, it treats not only of the structures of the insects, but also, at considerable length, of their biology, everything being set forth in the most interesting way. There is a good account of the cases of 'mimicry' involving these wasps. Thus the wasps of the genus *Nectarina*, in the neotropical region, belong to an assemblage of diverse insects of similar appearance, of which no less than twenty-eight are cited. Dr. Bequaert recognises the objections to the term mimicry as applied to these cases, and proposes to speak of homoeomorphy and homoeochromy instead, these terms merely referring to the observed facts, without suggesting any explanation. This seems to be an advantage, though perhaps the shorter words isomorphy and isochromy would be preferable.

In discussing the probable meaning of these resemblances, as related to natural selection, I think Dr. Bequaert takes too narrow a view. Thus he refers to the American *Pachodynerus nasidens*, which has been accidentally introduced into the Hawaiian Islands, where it has become extremely abundant. Now the Hawaiian Eumenid wasps have a totally different appearance, and so, he argues, *P. nasidens*, removed from the protection of its mimetic group, ought, according to the current theory, to be severely handicapped. This argument I think has no validity, in view of the great difference in the vertebrate fauna. *P. nasidens*, along the Hawaiian coasts, is not only without the natural enemies it left in tropical America, but also is relatively free from enemies of any kind, as will be readily appreciated by anyone who has travelled in both regions.

There is, however, another aspect of these matters which is not generally considered. Insects are extremely prolific, and the balance of Nature, under normal conditions, provides for the destruction of by far the greater part of each generation before the period of reproduction. This destruction is necessary for the insect itself, in order to avoid over-population and resulting starvation. Hence the normal survival rate, according to the species, may be only ten per cent, or five per cent, or even less than one per cent of the offspring hatched from the egg. It is astonishing that, working on such a narrow margin, insects in general survive as well as they do. I recall some observations on Coccidæ (scale insects) made in New Mexico many years ago. Certain species occur on the mesquite and other shrubs which exist in great abundance over many thousands of square miles of country. Yet the coccids are only found in isolated patches here and there. They are destroyed by their natural enemies, but the young larvæ can be blown by the wind or carried on the feet of birds, and so start new colonies which flourish until discovered by predators and parasites. This game of hide-and-seek doubtless results in frequent local extermination, but the species are sufficiently widespread to survive in parts of their range, and so continue indefinitely.

We may suppose, then, that neither 'mimicry' nor any other mode of protection prevents the destruction of the larger part of each generation of insects; and such prevention, were it possible, would result, not in stable conditions, but in over-production and disaster But during any lengthy period, the species of insects will show fluctuation in the number of surviving individuals, and must from time to time come very near to extinction. Indeed, very many do become extinct, as we can infer from a study of the fossil records During these recurring 'hard times', slight advantages or disadvantages are of critical importance and may decide between survival and extinction But at other times of greater prosperity, they seem to be of little consequence If a 'critical' period occurred once in a thousand years, it would suffice for all the purposes of the theory

Another important consideration is the frequency of parallel and 'convergent' variation; the continual recurrence of similar structures, patterns and colours in different genera and species These phenomena indicate the existence of deep seated tendencies, which find expression without any reference to immediate utility In this way it often happens that diverse insects, even in different localities, come to look alike, and if 'mimicry' is promoted by natural selection, these resemblances are the raw material on which it works

Bilateral Gynandromorphism in Feathers

IN recent publications Lillie and Juhn[1], Domm, Gustavson, and Juhn[2], and Lillie[3], have suggested an explanation of the bilateral gynandromorphism of certain individual feathers. This explanation is based upon the idea that susceptibility to female hormone depends upon growth rate, being greatest for slow-growing and least for quick-growing feather tissue. These authors further describe the formation of the rachis by concrescence The rachis thus has a double origin, and its two sides were once the two halves of the collar. This description differs widely from the accounts of Strong[4,5] and of Davies[6].

Now it may be remarked that past growth rates can only be measured by the relation of the size of present to past structures, and that present growth rates cannot be measured at all It would seem, therefore, that the suggestion that in a bilaterally gynandromorphic feather the growth rates on the two sides of the collar were so different that, on the theory advanced by Lillie and his collaborators, female hormone could act on one side and not on the other, can only find a foundation in observation in one of two sets of circumstances. Either (a) the barbs on the two sides must be of different lengths, and the rachis curved, since one side of it has grown faster than the other; or (b) the feather germ must have an asymmetry of just such a kind and degree as to compensate for the difference in growth rate and give a straight feather. This asymmetry might be in fact a displacement of the ventral growing point from its theoretical position diametrically opposite the forming rachis; then the more rapidly growing side could get carried out of the region of growth so much sooner than the more slowly growing side, having less distance to travel, as to be the same size or even smaller.

The condition (a) is certainly not fulfilled in fact. The bilaterally gynandromorphic feathers shown in Figs. 51 and 52 by Lillie and Juhn[1] are straight, as are those figured by Cook, Dodds and Greenwood[7]. The retrices of Bond's pheasant[8] have a curvature which is not in constant relationship to their sexual dimorphism. There remains condition (b). Lillie and Juhn[1] figure an asymmetrical germ (Fig. 8), which gives rise to a feather symmetrical in shape, so that by their account its growth must have been different on the two sides. The relationship of colour to growth rate is, however, not shown by this example as the feather is also symmetrical in colour.

While the work of Lillie and Juhn and the other authors referred to is clearly of the very greatest interest and importance, it seems, in the light of the foregoing remarks, that the concept of the formation of the rachis by concrescence may lead to difficulties in the interpretation of sexually dimorphic colours which might be avoided by the adoption of other accounts of feather development, and that growth rate may not play quite the part assigned to it in determining the susceptibility to female hormone of the parts of the feather.

It is hoped soon to undertake work in this Department involving in particular an analysis of the relationship of asymmetry in the germ to asymmetry in the feather, and to review in the light of any evidence gained the physiological principles concerned, whether they be of growth rate, or of differentiation rate, or of a kind not yet apparent.

Designation of the Positive Electron

I HAVE been hoping that, following Lord Rutherford's proposal of a name for the heavy isotope of hydrogen, someone would suggest a more satisfactory word than 'positron' for the positive electron. Since, however, no better qualified reformer has appeared, may I raise the question before it is too late? 'Positron' is ugly; it offends literary purists by its hybrid character, and it not only bears no relation to the established name of the associated particle, the electron, but even suggests that that particle should be called the 'negatron', which fortunately it is not.

In order to balance destructive by constructive criticism, I venture to propose the name 'oreston' for the newcomer. The word is euphonious, pure Greek, and since, in one of the most beautiful of Greek stories, Orestes and Elektra were brother and sister, it implies an appropriate relation between the two particles The name found favour among many physicists in Pasadena where Anderson first obtained evidence of the particle, when I mentioned it there last year. I do not propose, however, further to urge its claims, the purpose of this letter being mainly to cleanse the language of 'positron', and only incidentally to nominate a substitute.

Active Nitrogen and the Auroral Spectrum

IN my letter in a recent number of NATURE[1] I described an afterglow in nitrogen in which the first negative bands of N_2 were present, and in which the excitation of the first positive bands was different from that hitherto observed in nitrogen afterglows. At the time the letter was written, no photograph of the afterglow intense enough to print had been obtained. Fig. 1 shows a photograph of the spectrum of the afterglow which has been obtained since then, and it is to be noted that with the exception of the green auroral line, the afterglow spectrum is remarkably like the auroral spectrum. In my first letter it was stated that the second positive bands were completely missing from the afterglow, and that was true of the plate which was described in that letter, but a trace of the second positive group can be very easily seen on the present plate and they have been obtained with considerable intensity on a plate taken on a small quartz Hilger spectrograph. The arrows on Fig. 1 point to first positive band sequences which originate on $V' = 16, 17, 18$, etc., and it is seen that these sequences are present on the afterglow plates also.

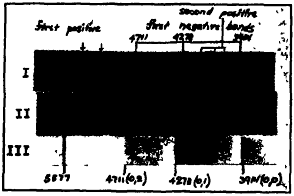

FIG. 1. I, Direct discharge (panchromatic plate); II, afterglow (Eastman astronomical green plate); III, aurora borealis (dispersion different from I and II).

Further experiments are now in progress in order to obtain better pictures of the first positive bands in the green, red and the photographic infra-red.

Age of Sub-Crag Implements

MR. J. REID MOIR has recently directed attention to an interesting series of worked flints found beneath the Red Crag, exhibited at present in the British Museum[1]. Adhering to one of these flints is some ferruginous sandy material which Mr. Moir regards as Diestian, since it resembles the sandstone of which the well-known Suffolk Boxstones are composed. Thanks to the courtesy of Mr. Reginald Smith, I have had an opportunity of examining this specimen. The encrusting material is an iron-cemented sand which appears to me to bear a stronger resemblance to Red Crag sand than to Boxstone material. The quantity of sand is too small to permit mineralogical analysis; moreover, such a process would destroy the evidence. Even if it were proved to be Boxstone detritus, the possibility of its having been re-deposited in Red Crag times would have to be seriously considered.

Mr. Moir bases interesting speculations on the possibility of the rostro-carinate implement in question being pre-Diestian, that is, pre-Pliocene. In this connexion, it is important to bear in mind that the British representatives of the Continental Diestian deposits are the Lenham Beds (Early Pliocene) of Kent and Sussex, and not the Boxstones of Suffolk, as Mr. Moir states. Our knowledge of the fauna of the Lenham Beds has been increased by discoveries made during the last few years, and recent investigations have served to emphasise the greater age of the Boxstone fauna. The latter is regarded by many geologists as Miocene; in fact, some of the mollusca are apparently related to Upper Oligocene forms. Mr. Moir's arguments would therefore imply that the maker of the rostro-carinate implement lived in times not later than the Miocene.

Ernst Haeckel

MANY scientists will have read with keen interest Prof. MacBride's delightful sketch of Haeckel's work in NATURE of February 10. As he points out, Haeckel's career belongs to the heroic stage of the history of the theory of evolution; certainly few men have been subjected to greater obloquy for promulgating that or any other doctrine. When his "General Morphology" appeared, it was met with "icy silence"—a reception which the impetuous and combative Haeckel could not tolerate. He would have preferred hostile criticism, rather than indifference; and to this indifference on the part of his fellow-scientists can be traced the commencement of that series of popular works on evolution which were met, not with "icy silence", but with fiery blasts from scientists and laymen alike.

At one period of the controversy, Haeckel felt that his presence at Jena was jeopardising the good name of his beloved university, so he offered to resign his chair; but the head of the governing body replied: "My dear Haeckel, you are still young, and you will yet come to have more mature views of life. After all, you will do less harm here than elsewhere, so you had better stop here." In point of fact, Jena never forsook Haeckel and Haeckel never forsook Jena, despite the flattering offers he received from the Universities of Vienna, Würzburg, Bonn and Strasbourg; and he died there, not in 1914 as mentioned by Prof. MacBride, but on August 8, 1919. An obituary notice appeared in NATURE of August 21, 1919.

W. H. BRINDLEY

Glossop, Derbyshire.
Feb. 9.

I AM sorry that I made a slip in giving the date of Haeckel's death. I thank Dr. Brindley for correcting me.

E. W. M.

Research Items

Moravian Racial Types. Prof. V. Suk contributes remarks on the value of selective study in the anthropometric investigation of a population as a means of distinguishing ancestral types, to a study of groups of people in Moravian Wallachia by Dr. K. Augusta which has been published by the Faculty of Sciences of the Masaryk University. Two groups were investigated in a population which has long lived in isolation in conditions which do not invite immigration. The traditional mode of life is agriculture, woodcraft, or herding pursued in woodland clearings. The people here specifically called "Valaques", according to recent theory based on linguistic evidence, are partly of Slovak, partly of Rumanian origin. The principal results of Dr. Augusta's anthropometric examination go to show that they are of mixed origin. Taking the two groups together, they show a medium stature (165·9 cm. and 167·1 cm.), they are brachycephalic (85·2 and 85·8), while the mean circumference of the head increases proportionately with increase in growth of stature. The face is mesoprosopic and the nose lepto- to mesorrhine (69·7 and 70). In pigmentation the eyes most frequently are grey or greenish, while the hair is light brown, next in frequency coming dark brown, and then blond, which, however, is rare, showing only 1·0 and 2·7 per cent. 'Pure' types are rare and the most common by far is the 'mixed light brown'. In the valley of *Dinotitza*, where the selective method of Prof. Suk was employed and not the statistical method on which the figures above were based, a considerable percentage was found of a type differing from the remainder of the population, darker, taller and more pronouncedly brachycephalic, showing all the marks of a Dinaric origin. This confirms the view that the population of this part of Wallachia is of a different somatic origin from the rest of the population. Its derivation must be sought in Rumania.

The Australian Oyster. T. C. Roughley in his paper, "The Life History of the Australian Oyster, *Ostrea commercialis*" (*Proc. Linn. Soc. New South Wales*, 58, Parts 3 4, 1933), studies the Australian edible oyster of commerce in great detail. This species appears to be confined to the Australian coast, its range extending from the far North Queensland coast to so far south as Wingan Inlet in Victoria. It thrives best in estuaries fed by much fresh water. Spawning always takes place on the chief bed studied (Port Macquarie) during spring tides when two or three hours on the ebb and often when a heavy sea is running outside, the temperature being usually 72°–76° F. In other places the oysters appear to spawn partially at intervals, and spawning proceeds daily or almost daily during the whole of the spawning period over five months. There is, however, great irregularity in the spawning of these New South Wales oysters, the reason probably being that the bulk of the oysters are grown in the tidal zone where temperature fluctuations, varying from cold water to hot sun in the course of a few hours, are enormous. A sex change is indicated in this species by the fact that practically all, if not all, young oysters spawn for the first time as males. Nine oysters were found (1–3 years) which contained both ova and sperms in the gonad. The determination of sex in this oyster does not appear to be governed by the amount of food available.

Feeding of the Fairy Shrimp. A. G. Lowndes has recently recorded observations on the feeding mechanism of the fairy shrimp, *Chirocephalus diaphanus* (*Proc. Zool. Soc.*, Lond., Part 4, 1933). By keeping the animal in a fixed position while causing a current of water to flow past it at the rate of two feet per minute (the normal rate of swimming of the shrimp), the movements of the appendages under approximately normal conditions can be observed. The author has also employed the polygraphic process, that is, taking photographs about 20 per second, by means of which the movements of the limbs can be recorded. He states that the commonly accepted view that *Chirocephalus* feeds chiefly on suspended particles is incorrect; its chief food consists of detritus. The larger food particles, for example, filamentous algæ, leaves of mosses, etc., are not sucked into the median ventral groove between the appendages, but are pushed in by the endites and pushed towards the mouth by the spines and setæ on the basal endites or gnathobases, which may act in apposition. Suspended particles drawn into the median groove cannot settle there by reason of the increase in the rate of flow as the groove narrows, nor is it likely they can be caught by a secretion of mucus. The movement of the limbs is irregular and only roughly metachronial. Any account of feeding which demands precise co-ordination of the limbs is untenable. The exopodite, regarded as the chief swimming limb, functions as a propeller and not as a paddle. Sars's view, that the primary function of the phyllopod post-oral limb is respiratory, is upheld (see also p. 329 of this issue).

Fungi Imperfecti. Referring to a notice in NATURE of December 16, p. 936, of Mr. J. Ramsbottom's presidential address to the Quekett Microscopical Club, in which the suggestion was made that many of the Fungi Imperfecti are mutants from heterothallic strains, Mr. H. A. Dade, of the Gold Coast Department of Agriculture, in a letter to the Editor, describes some unpublished work of his which supports the suggestion. In 1928 he showed that the common tropical *Thielavia paradoxa* is the conidial stage of a *Ceratostomella*, *C. paradoxa*, which is heterothallic. So far, the perfect stage has been found only on the Gold Coast. After the publication of his account, he received numerous cultures from other countries which differed much in cultural characters though not sufficiently to merit specific distinction. Some few when mated with the original strains formed perithecia, others did not. Two vigorous Ceylon strains formed perithecia when crossed with the (+) and (−) Gold Coast strains, but not when mated together, the loss of this power presumably being due to mutation.

Practical Methods of Soil Heating. A good deal of attention has recently been focused on the question as to whether raising the soil temperature in glass-houses by artificial means would be a commercial proposition in Great Britain as it has been in Scandinavia. Investigations on the matter have been carried out at Cheshunt Research Station and the results recently described by Dr. W. F. Bewley (*J. Min. Agric.*, 40, 1047). Cables consuming 1 kilowatt per hour at 240 volts were laid 16 in. below the surface of the soil. Heat was applied from 10 p m until 6 a m for the first twelve weeks after planting In the case of tomatoes, those grown on the heated soil showed more rapid growth, cleaner roots, earlier flowering and quicker fruit maturation than the plants on the untreated soil, and in 1929 the total crop was 20 7 per cent higher in the former case. Similar promising results were obtained with cucumbers The chief problem, however, was cost The cables, which are expensive, deteriorate rapidly, and further, the annual renewal of cucumber beds necessitates relaying the wires each season Twisted strands of galvanised steel wire (14 s w G), however, showed no corrosion after three seasons and proved considerably cheaper The price of heating, even at ¼d per unit, also is high, since about 5 watts per square foot are required to raise the temperature 6° F. (from 66° to 72) Another and cheaper method of soil heating which gave promising results was that derived from an underground extension of the ordinary hot-water pipe system The temperatures found to give good results were 70°–75° F Further advice on the subject can be obtained on application to the Director, Experimental and Research Station, Cheshunt Herts

Colour Photometry The rapid extension of the use of coloured luminous electric discharge tubes for lighting and advertising purposes has raised into prominence the question of how best to measure the candle powers of coloured lights, and Mr. H Buckley and his colleagues at the National Physical Laboratory have tested the methods available The results at which they have arrived were communicated by Mr Buckley to the Illuminating Engineering Society in a paper read before the Society on February 20 The original method of comparing the brightness of two sources of different colours is both difficult and unreliable, but the newer 'flicker' method is easy to carry out and reliable The 'calculation' method, which depends on the determination of the energy distribution of the light source and on the effect which each colour produces on the eye, while it gives accurate results, is tedious and requires skilled work with a spectrophotometer Mr Buckley advocates the use of coloured screens the absorption of which throughout the spectrum is observed by the spectrophotometer and which when placed between a standard light and a photometer of either of the above types will give an approximate match with the coloured light to be measured A small field of view seems an advantage

Acid Catalysis in Non-Aqueous Solvents. A number of reactions are catalysed in watery solution by acids irrespective of the precise nature of the latter R P. Bell (*Proc Roy Soc.*, A, Jan) has studied the catalytic effect of a number of acids in solution in chlorobenzene, benzene and some other solvents. The catalysis in such solvents must be due to the acid molecule and not to the other products formed in presence of a dissociating solvent like water The reaction studied was the re-arrangement of *N* bromoacetanilide to form *p*-bromoacetanilide, and the reaction was followed by using the liberation of iodine from acid potassium iodide by the *N* bromoacetanilide It was found that the catalytic power increased in the same order as the strength of the acids, as measured by their dissociation constants in water. Picric acid occupies an anomalous position, possibly because of tautomerism in the picrate ion. Quantitatively, the catalytic power increases less rapidly than the dissociation constant in water, the values being connected by a 0 3 power law Very similar results were obtained from some less accurate measurements in benzene solution and from a few experiments in ethyl nitrate and ethylene chloride The rates of reaction in chlorobenzene are 10^4 10^5 times less than those calculated on the assumption that every collision is effective that takes place between a reactant molecule and a catalyst molecule with the proper energy of activation

Action of Solvents on Coal. Of the methods employed for studying the constitution of coal, none has been more popular than the use of solvents to separate constituents of different character The range of solvents used by different workers is large and the report on "The Action of Solvents on Coal" (Fuel Research Board Technical Paper No 37, H M. Stationery Office, 4*s* 6*d* net) containing a critical survey of work in this new field, supplemented by experimental study, will be useful to all engaged in this branch Unfortunately, the selective action of solvents is never clear-cut, and the character of coal shows infinite variety, leaving opportunity for great diversity of findings Even since the writing of the book, new complications have appeared in the discovery that some solvents can, by reaction or condensation, produce resinous matter which has at times been attributed to the coal Moreover, it has been shown that the portion capable of extraction can be considerably increased if the coal be first reduced to dimensions of the order of one micron

Reinforced Concrete Structures. Steel, with its great tensional, and concrete with its great compressive, strength, possessing similar coefficients of expansion, seem to have been intended for combination in structures Rules controlling the use of any form of construction must necessarily be framed on conservative lines in the absence of scientific data, and when wide application precedes detailed research caution is the more required, but experience gained shows that without impairing safety greater economy in the employment of these materials as re-inforced concrete is possible To meet this national need and the requirements of the London County Council, which is revising the London Building Act, a committee was set up by the Department of Scientific and Industrial Research under the chairmanship of Sir George Humphreys to consider improvements in the regulations for re-inforced concrete work, and this committee with the information on the better and more scientifically prepared materials now obtainable before it, has produced a code of practice based on present-day knowledge which will admit of considerable economies being effected An entirely new feature of these regulations is the permission of three grades of work allowing greater stresses, or, in effect, less material to meet the required stresses, where more care and skill is given as adjudged by the tests required on samples made as the work proceeds. The code defines the materials and details of construction allowed and gives the strengths to be shown by tests when called for Though actually only applicable to the area administered by the L.C.C., it is expected that the code will form a standard for use throughout the country. During the work of the committee, the investigation at the Building Research Station under Dr Stradling has proved a valuable asset.

Palestinian Prehistory

THE selection of archæological finds from the caves of the Wady al-Mugharet at the foot of Mt. Carmel, Palestine, now exhibited at the British Museum (see NATURE, Feb. 3, p. 169), repays careful inspection. By affording a comprehensive view of the results achieved since 1929 by the Joint Expedition of the British School of Archæology in Jerusalem and the American School of Prehistoric Research under the field direction of Miss D. A. E. Garrod, the exhibit fully confirms previous conclusions, based on the periodical reports, as to the importance of the excavations in these caves, not only for the prehistoric archæology of Palestine, but also for prehistory in general. The discovery of so large a number of skeletons of man of Neanderthaloid type, to whom Sir Arthur Keith would assign generic rank under the name of *Palæoanthropus Palestinensis*, and including the oldest known complete human skeletons, for which a geological dating as belonging to the Riss-Wurm interglaciation is given, would alone place these investigations in the first rank of scientific importance; but in addition they have brought to light a new civilisation and a new race, the Natufian, of late palæolithic or mesolithic age, in which remarkable features of racial character and culture open up suggestive lines of thought in connexion with prehistoric custom and belief and racial distributions.

The exhibits include examples of the small flakes of the Tayacian, comparable with implements from La Micoque, the Upper Acheulean hand-axe, the leaf-shaped point of the Lower Aurignacian, hitherto known only from Africa, Middle Aurignacian scrapers, comparable with those of Western Europe, and characteristic scrapers and gravers from the Upper Aurignacian. The Natufian culture, of which the first evidence was found in the Wady el-Natufa, whence the name, is well represented, among the more striking features being the remarkably elaborate composite head-dresses of shells which were found on the human skeletal remains, and the evidences of the beginnings of agriculture in the form of sickle blades and hafts. The latter are further noteworthy as including among their number two hafts ornamented with carvings of animal heads. These with other gravings on bone or stone are the first and indeed the only known examples of the art of stone age man to be found in Palestine.

The human bones show evidence of cannibalism. Sir Arthur Keith, in reporting on the human remains, judged them to be unique in racial character, but found that certain features suggested affinities with pre-dynastic Egypt. The Natufian faunal remains include the true horse, the Persian fallow-deer and the spotted hyæna, now found only south of the Sahara. The frequent occurrence of remains of the gazelle point to a dry climate and open country, contrasting with conditions in late Mousterian times when the abundant remains of deer suggest a forested area with copious rainfall.

It will thus be seen that the exhibition covers the complete sequence of Palestinian prehistoric cultures from Acheulean to Bronze Age, the last named apparently following on immediately after the Natufian, or, in years, a period ranging from about 100,000 years ago to approximately 6000 B.C.

Future of Artificial Lighting

MR. C. W. Sully, president of the Illuminating Engineering Society, gave an interesting address at the British Industries Fair at Birmingham on February 22. He pointed out that although great progress has been made in illumination during the past fifty years, yet compared with some other applications of science, such as transport or telephony, its progress appears relatively slow. There is no occupation we can pursue and no recreation we can indulge, in which the eyes are concerned, that does not offer problems in lighting. Too frequently progress takes place in a succession of jerks. As an example, consider the headlights of a motor-car. With increased speed stronger lights were demanded. Concentrated beams, well directed towards the objects requiring illumination, served the driver of the car excellently. But it was soon found out that these beams were a menace to oncoming traffic and glare from headlights is still an outstanding problem.

New devices, new methods and new materials are constantly changing the technique of lighting and developing new sections of industry. The new methods of utilising gaseous tubes producing various colours, the new electric discharge lamps, the continually extending use of stainless steel for reflectors and the applications of the new synthetic plastic materials to lighting fittings may be mentioned. In some cases buildings like cinemas and theatres are expressly designed for use by artificial light. Natural lighting has become a minor matter and is in some cases entirely omitted. In the case of blocks of buildings in congested city areas, access of daylight is imperfect and so costly as to be almost prohibitive.

It is accordingly now being suggested that, in these circumstances, the effort to furnish natural lighting should be abandoned, and that efforts should be concentrated on the provision of adequate artificial lighting. The question arises as to whether there is anything inimical to health in this procedure. This is a question of moment to the lighting industry. The ever-increasing height of buildings and other developments will probably accentuate the need for artificial lighting at the lower levels.

The city of the future has been visualised as consisting mainly of immense flat-topped buildings, rising in terraces from the ground-level, the upper walks being reserved for pedestrians, who would be provided with connecting bridges crossing the roadways at intervals. Roadways at the ground level would be used exclusively for motor traffic. If this is the trend of development, then lighting at the lower levels would be mainly artificial. A suggestion has been made that football, athletic contests and other sports may, in the future, take place in vast covered stadiums where diffused artificial lighting, resembling light from the natural sky, would be attainable and where difficulties arising from our capricious weather would be largely eliminated.

Mr. Sully also discussed the lighting of schools and factories. In school buildings the natural and artificial lighting is often very defective In many recent factories excellent equipment is installed, but in some of the older buildings, antiquated and imperfect arrangements still persist Britain, almost alone amongst the civilised countries, has even now no specific requirement of adequate lighting in its Factory Act, although this step was advocated twenty years ago by a Departmental Committee

Mr Sully thinks that street lighting lags behind modern requirements. In a factory, five foot candles is regarded as essential for fine work According to the B S.I. specification, one per cent of this is given as the candle power sufficient for a moderately lighted street This only represents 1/10,000th of the average value of unrestricted daylight from an overcast sky No wonder the accident risk by night is greater than that by day The problem of public lighting is complicated by the fact that many roads now fulfil functions quite different from those for which their lighting was originally designed In Mr. Sully's opinion, the lighting of the King's highway is a national rather than a parochial duty The Ministry of Transport should assume a greater degree of responsibility for its illumination

Association of Technical Institutions

THE annual general meeting of the Association of Technical Institutions was held in the Drapers' Hall, London, on February 23–24 During the first session Mr. Will Spens, Master of Corpus Christi College, Cambridge, and newly-appointed chairman of the Board of Education's Consultative Committee, who was elected president of the Association for the year 1934, delivered his presidential address

At the outset, Mr. Spens suggested that he was unable to enter into a discussion how to enhance the value of technical education, since his knowledge of that, and of industry and commerce, was not very considerable However that may be, his address demonstrated the closeness and profundity of his knowledge of the field of education generally He insisted on the value of literary studies in teaching men to think he would not, therefore, have traditional academic education weakened, although he thought too much emphasis had been placed upon it. He pleaded for research in applied science, but stressed the need for inculcation of scientific *method* rather than the simple acquisition of scientific knowledge.

Among the papers read during the following sessions was one on "Education for Commerce from the Employer's Point of View" by Mr. F. Hickinbotham, of Birmingham He emphasised the point that commercial education lags behind other branches of technical education because of the fact that the need for specialised education for commerce arose later in commerce than in the sciences and skilled trades It is impossible, for example, to practice chemistry, pharmacy, engineering, etc, without a body of specialised knowledge, but many branches of commerce do not require this specialised knowledge. hence educational facilities have developed slowly The present need for systematic instruction, however, is occupying considerable attention Mr. Hickinbotham believed that the efforts which are being made to introduce commercial subjects into the secondary school curriculum were mistaken In the secondary school the pupil should receive a general education, and afterwards take a one- or two-year full-time course in a commercial college, where instruction given by teachers with commercial experience would be better than that given by teachers who acquire their knowledge merely from books One of the greatest needs of the world is to break down the barriers of nationalism and to promote a spirit of internationalism To this end the first essential is to know the language the other man is speaking Languages, therefore, should find an important place in all commercial courses

Mr Hickinbotham's paper had a special interest since the thought now being given to commercial education is a reflection of some of the wider anxieties of our civilisation. The science of production has developed swiftly and efficiently we have scarcely begun to understand the science of distribution Those responsible for technical education are alive to their responsibilities in this connexion. Evidence of this was submitted as the meeting proceeded, when a "Report on National Certificates in Commerce", prepared by a joint committee of the Associations of Technical Institutions, of Principals of Technical Institutions and of Teachers in Technical Institutions, was accepted While it does not yet seem possible to draw up a scheme for national certificates in commerce such as those applying to engineering, chemistry, etc, the report goes far to establish means by which it is hoped that national certificates in the full sense of the phrase may ultimately be available.

Dog Breeding for Show Points

"WE have bred dogs for all sorts of show points, but we have never considered whether our principles of breeding have been to the advantage of the dog itself We have thought only of our own profit." So concludes the editor of the *Countryman*, who asks whether or not our dog breeding principles so far, judged entirely from the dog's point of view, are not a bit 'low down' and, further, why should not some breeding now be done for intelligence? In a series of articles now appearing in this quarterly review, these questions are considered by a number of people Dr. Darling expends most of his space in proving to his own satisfaction that he is quite unable to decide as to what could be regarded as intelligence in the dog, and argues that in any event the experiment suggested has already been carried out with the working hill collie. But he agrees with the editor of the *Countryman* in stating that there can be no defence for many show points. The standard of the St Bernard is merely acromegaly, that of the bulldog achondroplasia; the toy dog is hyperthyroidic, and terriers microcephalic. Prof. L C. Dunn, of Columbia University, in a very well-written article, suggests that it is not intelligence that is being discussed but educability, and that this, possibly, is not associated with originality and critical judgment He then outlines the sort of experimental procedure which might be adopted if the experiment suggested were undertaken Prof. Tait, of McGill University, following the lead of Prof Dunn, replies without answering, which is perhaps just as well

Surely, when the editor of the *Countryman* uses the phrase "principles of breeding" he means the objectives in breeding, for the principles are the same whether one breeds for intelligence or for intestinal length; and what does he really mean by "the dog's point of view"? Would a bulldog prefer to be an Alsatian, or the Pekinese a whippet? Dr Darling's views concerning the extravagant and the fantastic make him remarkable amongst men It is solely because man has always been attracted by these that he has perpetuated them to produce such pleasing variety amongst domesticated birds and beasts He may not like the Pekinese, but many people do, and so does the Pekinese, and he is far from miserable so far as we can judge We have selected and fixed by breeding those characters of the dog that pleased or advantaged us, quaintnesses of all kinds, as well as special abilities Every kind of combination of form and behaviour exists By segregation and recombination new breeds could be manufactured, and by continued selection most of the qualities exhibited by the dog could be emphasised That such a great variety of types exists is merely a reflection of the fact that different people have different ideas as to what constitutes attraction in a dog. The world would be a much duller place if all the dogs in it were hill collies

There is, however, the germ of a really serious question in the musings of the editor of the *Countryman*, for show standards commonly do tend to demand a grade of physiological extravagance that is distinctly undesirable and, in certain instances, even definitely pathological Quite serious defects and derangements can easily be bred into a stock to its detriment deafness in the bull terrier, cleft palate in the bulldog, disharmony between the size of pelvis and the size of fœtus in the 'toys'. The exceedingly long ear-flaps of the spaniel lead to the development of hæmatomata and canker; the short bowed legs of the Scottie are associated with the development of interdigital cysts; the short-faced breeds suffer sadly from respiratory diseases, for the reason, it may be assumed, that they lack a proper air filtering and warming apparatus; and the fleece of the Old English sheep dog is the ideal home of external parasites No show standard should be allowed to continue which inevitably demands a high lethality in the breed or an obvious discomfort to the individual

University and Educational Intelligence

ABERDEEN —Prof James R Matthews, professor of botany in the University of Reading, has been appointed regius professor of botany in succession to the late Prof. W. G Craib

LONDON —Mr David Brunt, since 1919 superintendent of the Army Services Division at the Meteorological Office, has been appointed University professor of meteorology (Imperial College—Royal College of Science) as from October 1, 1934. Dr. R. J. Lythgoe, since 1928 honorary lecturer at University College, has been appointed University reader in the physiology of the sense organs at the College as from October 1, 1933.

The title of 'Fellow of University College, London' has been conferred on the following, among others: Mr. C B Collott, chief mechanical engineer of the Great Western Railway; Dr E Mallett, principal of the Woolwich Polytechnic and head of the Electrical Engineering Department, formerly reader in electrical engineering, City and Guilds (Engineering) College, Mr H. J. Page, in charge of the Imperial Chemical Industries Experimental Station for Agricultural Research at Jealott's Hill, formerly head of the Chemical Department of the Rothamsted Experimental Station; and Dr A S Parkes, a member of the staff of the National Institute for Medical Research, Mount Vernon, Hampstead, formerly Sharpey scholar and honorary lecturer in physiology, University College, London

The title of 'Honorary Fellow of University College, London' has been conferred on the following Prof. Karl Pearson, professor of applied mathematics and mechanics at University College, London in 1884–1911, Galton professor of eugenics in the University of London in 1911–33, and Sir Flinders Petrie, Edwards professor of Egyptology at University College, London, in 1893–1933.

OXFORD —At the meeting of Congregation held on February 20, a decree moved by the Master of Balliol postponing the operation of certain portions of the Forestry Statute which was passed by Congregation on February 13 until August 1, gave occasion to a further discussion on the merits of the Statute Prof R V Southwell opposed the decree on the ground that the new Forestry Committee should have the opportunity of expressing its opinion on the question of the site He also pointed out that under the new Statute it was uncertain whether the professor of forestry would be able to exercise an effective control. Moreover, under the conditions of the Statute, the security of tenure of the staff of the Institute was incompletely provided for The honour of the University would not have been compromised by the rejection of the Statute, inasmuch as Congregation had a perfect right to a free vote on the matter

Dr H V Denham, director of the Institute of Agricultural Engineering, said that the experience of his department showed that the new forestry scheme might be expected to work successfully Prof F. A Lindemann complained that the Boards of Faculty concerned had not had the opportunity of seeing the Statute before it was proposed The Master of Balliol, replying on the whole debate, reminded the House that objections to the Statute should have been brought in the form of amendments, and not have been deferred until the Statute had passed.

The Vice-Chancellor having ruled that even if the decree were thrown out, the existing Board of Governors, and not the new Forestry Committee, would be concerned in the question of the site, the opposition was withdrawn, and the decree passed without a division

At the same meeting of Congregation, the gift by the Royal Society of £200 for astrographic work in the University Observatory was gratefully accepted.

In the *University Gazette* of February 21, the Hebdomadal Council gives notice that it has appointed a committee to collect evidence of the probable future building requirements of the University.

Science News a Century Ago

Polarisation of Light from the Sky

At a meeting of the Cambridge Philosophical Society on March 3, 1834, the Rev. Temple Chevalier described experiments which he had made on the polarisation of light from the sky. The general results were that light from the clear sky is polarised; that the effect begins to be sensible at points 30° distant from the sun, and that the maximum of polarised light proceeds from points at 90° distance from the sun; a fact which seems to indicate that the reflection which occasions the polarisation, takes place at the surface of two media as nearly as possible of the same density.

On March 10, Prof. Airy gave an account before the Society of experiments on the same subject. It appeared that the light is polarised in a plane passing through the sun, and that the plane of polarisation is not reversed in approaching the sun, as had been formerly suggested by M. Arago. Prof. Airy found that he could observe the polarisation within 9° of the sun, in a horizontal direction, but that above and below the sun the traces disappeared at a distance considerably greater. It was found in the course of these experiments that very rough surfaces, as a stone wall, a gravel walk, a carpet, produced some polarisation by reflection; and that the plane of polarisation in all cases passed through the point of reflection and the source from which the light came.

Forests of Holderness

On March 4, 1834, John Phillips, then keeper of the York Museum and professor of geology in King's College, London, read a paper to the Yorkshire Philosophical Society on the ancient and partly buried forests of Holderness. The country of Holderness, he said, was a large triangular district, bounded on one side by the "German" Ocean, on another by the estuary of the Humber, and on the third by the declining plane of the chalk. It was not properly a level but rather an undulating low district with isolated hills and devious ridges. The winding hollows which embrace the hills in the southern part of Holderness were generally filled with sediment from the tide which, if allowed free access, would cover them five, ten or more feet deep.

Phillips's paper had been written as a result of two visits to the district when a large drain nearly parallel to the River Hull had laid bare a considerable number of plant accumulations at a level greatly below that of the water of the Humber.

Hydro-Oxygen Microscopic Exhibition

On March 5, 1834, a hydro-oxygen microscopic exhibition was opened at Mr. Stanley's Rooms in Old Bond Street. Speaking of the exhibition, the *Times* declared it to be the most interesting the metropolis could boast, and one which to the man of science and the searcher after the mysteries of Nature was invaluable, by opening up sources of knowledge which, but for the powerful agency employed, must otherwise remain closed against all attempts at investigation. For those readers who had not seen the microscope, it was explained that it magnified the common flea to a size considerably greater than the largest elephant. The objects exhibited included the wings of insects and crystals of saline substances; special interest being displayed in some beautiful crystals of chromate of potash. "The ingenious gentlemen who superintend the exhibition likewise display some examples of the polarisation of light, which exhibit all the colours of Newton's scale of tints. These experiments attracted much attention from the scientific gentlemen who were present."

Royal Society, March 6, 1834

On this date the reading of a paper was commenced (Mr. Brunel in the chair), entitled "On the Structure and Functions of tubular and cellular Polypi, and of Ascidiæ" by Joseph Jackson Lister, F.R.S. The reading was resumed and concluded (Mr. J. W. Lubbock in the chair) on March 13, following. [Sir Joseph (afterwards Lord) Lister, who was one of the four sons of Joseph Jackson Lister, wrote the biography of his father in the "Dictionary of National Biography".] The paper was published in full, under a revised title, with four plates, in the *Philosophical Transactions* for 1834. Its modest opening sentences run thus:—"The more obscure functions of vitality are of such difficult investigation, and possess at the same time so high an interest, that anyone contributing, in however small a degree to increase our information regarding them, may hope to meet with indulgence. Having observed the existence of currents within the tubular stem of a species of *Sertularia*, their investigation led to additional particulars relating to that family of Zoophytes, and other compound animals more or less resembling them, some of which it is hoped may be new in physiology." The drawings in illustration were traced by a camera lucida slid over the eyepiece of the microscope; and the author recommended its use to other observers because of the facility with which correct graphic records and measurements might be obtained.

Sir Edward Parry in Australia

Admiral Sir Edward Parry, the distinguished arctic explorer, was as well known for his philanthropy as for his discoveries. The care of those under him was always a matter of great concern. After making three voyages in search of the North-West Passage, and holding for four years the office of hydrographer to the Navy, he was appointed Commissioner of the Australian Agricultural Company in New South Wales. This concern had been incorporated by Royal Charter and granted a million acres of land, for the purpose of promoting the production of fine merino wool and other agricultural produce. Its affairs, however, had been sadly mismanaged, and with the sanction of the Admiralty, Parry accepted the office of Commissioner. He left the Thames in July 1829, landed at Sydney in December, and shortly afterwards took up his residence at Carrington, on the harbour of Port Stephens, about ninety miles north of Sydney. Here he found full scope for his activities and it was afterwards said: "At Port Stephens he found a wilderness but left it a land of hope and promise." He laboured incessantly to improve the lot of the settlers, the convicts and the aborigines, opening schools, promoting games, and himself frequently conducting divine service. On March 9, 1834, he preached a farewell sermon which led his successor, Colonel Dumaresq, to remark to a friend: "I have travelled a great deal during my life, and mixed much with men, but," pointing to Sir Edward, "in all my travels I never met with his equal."

Societies and Academies

London

Royal Society, February 22 A S Parkes and M Hill Effect of absence of light on the breeding season of the ferret Bissonnette's discovery that additional illumination would induce œstrus in anœstrous ferrets has naturally led to speculation as to what controls the onset of the breeding season in the normal ferret An obvious interpretation of Bissonnette's results was that the beginning of the breeding season of the normal female ferret in April is due to the increasing duration of daylight This hypothesis was put to experimental test by keeping ferrets in darkness from the latter part of anœstrus onwards From the results it is concluded that while additional light will induce œstrus in anœstrous animals, the onset of the breeding season in the spring is not dependent on the increasing length of daylight L E. S Eastham Metachronial rhythms and gill movements in relation to water flow in the nymph of *Cœnis horaria* (Ephemeroptera) By means of the oscillatory movements of four pairs of gills, the nymph produces a flow of water across the body from one side to the other, the current being reversible The gills rise and fall in periodic motion, and in so doing they traverse an elliptical path and, by a pivoting movement, move at an angle with their own path of motion The metachronial rhythm in the movements of the gills along each side of the body is from before backwards, but the gills of one side in motion are always out of phase with those of the other A transverse rhythm therefore exists across each pair of gills, which rhythm is in the direction of the water flow across the body It is reversed when the direction of the water current is reversed Reversal of flow is associated with changes in the method of pivoting of the gills , their manner of overlapping as members of pairs , the direction of the transverse rhythm over the gills F J W Roughton The kinetics of hæmoglobin (4–7) The methods of Hartridge and Roughton for the study of the velocity of rapid reactions were first applied by them to the reaction between hæmoglobin and oxygen The present papers extend the work to the 'sister' reactions of hæmoglobin with carbon monoxide. Velocity equations have been arrived at for (i) the combination of carbon monoxide with reduced hæmoglobin, $CO + Hb \rightarrow COHb$, (ii) both phases of the reversible reaction, $CO + O_2Hb \rightleftharpoons O_2 + COHb$ The results do not accord theoretically with a chemical mechanism of the type $Hb_n + nCO \rightleftharpoons Hb_n (CO)_n$, but can in part be interpreted by Adair's intermediate compound hypothesis, according to which the reaction of oxygen or carbon monoxide with hæmoglobin takes place in successive stages New possibilities are, however, brought to light, notably when trying to explain the paradoxical observations that *p*H is almost without effect upon either phase of the reversible reaction $CO + O_2Hb \rightleftharpoons O_2 + COHb$

Cape Town

Royal Society of South Africa, October 18 A Ogg and E N Grindley: Declination at the University of Cape Town Magnetic Observatory August 1932–August 1933 A full programme of photographic recording of the declination, the horizontal intensity and the vertical intensity by two sets of la Cour instruments has been maintained at the Observatory during the year The daily variation curves of declination for each month, which have been determined, show interesting changes from month to month The curve for August 1933 is exactly similar to the curve for August 1932, with a secular variation of 4 2 minutes B F J. Schonland and B Delatizky Continuous recording of cosmic ray intensities. Instruments for obtaining continuous hourly measurements of the intensity of the cosmic radiation have been installed at the University of Cape Town. The records are obtained automatically. The station forms part of the international scheme for the study of variations in intensity of the rays with time organised by a European committee, and is the only one in the southern hemisphere. The station has been in continuous operation since February 1933, and will be carried on for another year The accuracy of observation is 0 1 per cent D M Beach · Phonetics of the Hottentot language The paper is based on the analysis of the pronunciation of more than a hundred Hottentot speakers, representative of all the Nama tribes, as well as Bergdama, Korana and Griqua. The Nama dialect is taken as a standard and described in detail Hottentot is a tone-language of the Chinese type, and there are six inherent tonemes of roots H A. Shapiro and H Zwarenstein. A rapid test for pregnancy on *Xenopus Laevis* Early morning urine from women is precipitated with 96 per cent alcohol. The precipitate is extracted with ether to remove œstrin and toxic substances, and the residue is then dissolved in distilled water 2–3 c.c. of the aqueous extract is injected into each of four female South African clawed toads. 12–18 hours later a positive reaction is indicated by either (*a*) extrusion of macroscopic ova through the cloaca, or (*b*) post-mortem examination of the animal (in the absence of ovulation), when one ovum or more will be seen in either or both of the oviducts respectively. Correct positive tests have been obtained as early as 20 days after the first missed menstrual period.

Geneva

Society of Physics and Natural History, November 2. C. E. Guye: Molecular dissymmetry and micellar dissymmetry. The author refers to the works of Curie on this subject. The action of the isolated molecules or of the large directed molecules should be favourable to the production of dissymmetry in the medium which surrounds them, and hence the molecules have more numerous possibilities of action in this medium. In this connexion, the author considers the results of work carried out on colloids by Lumière, De Vaux and others, who have shown that the vital element of the cell or of the serum would not be the micelle element but rather the molecular element He quotes a certain number of facts in favour of the molecular theory of the vital element. A. Schidlof · The constitution of heavy nuclei J Weigle A precision method for measuring rhombohedral lattices. A method of extrapolation of the experimental results gives an average of the exact values of the X-rays for the constants characterising non-cubical lattices This method applied to sodium nitrate gives for the wave-lengths of the edges of the elementary rhombohedron 6 3108 × 10^{-8} cm and 47° 15′ 59″ for the angles which they form between them H Saini The thermal expansion of silver by X rays The author has determined the coefficient of expansion of silver by X-rays between 20° C and 300° C using a Seeman-Böhlin chamber specially constructed for the study of expansions Results. lattice constant of silver at 18° C, $a = 4\ 0772 \times 10^{-8}$, coefficient of expansion $(19\ 1 \pm 0\ 2)10^{-6}$ degrees^{-1} E Friedheim Two natural reversible oxido reduction systems Lawson and juglon. The pigment of the sarcocarp of nuts The Juglan walnut and the pigment of *Lawsonia Inermis*, Lawson, or henna, are systems of reversible oxido-reduction Their normal potential is for *p*H 7 0 at 20° C, $E = +0\ 033$ (Juglan), $E = -0\ 139$ (Lawson). Since the juglon in the living plant is found essentially in the reduced state and the Lawson in the oxidised state, the oxido reduction potential of the plant cells in question is determined by the two values indicated E. Friedheim. Concerning the mechanism of the respiratory catalysis by systems of reversible oxido-reduction. The two reversible natural pigments, Lawson and juglon, increase the respiration of the red corpuscles of the rabbit by about 600 per cent, juglon forms methæmoglobin but Lawson does not The respiratory catalysis of the red corpuscles by systems of reversible oxido-reduction is thus independent of the formation of methæmoglobin as would follow from the theory of Wendel and Warburg The formation of the methæmoglobin is in fact concomitant, depending on the oxido reduction potential level and in addition, on conditions of kinetic order J. J. Pittard: Observations concerning the proportion of gold in the water courses of the Canton of Geneva. The author has proved that the stream is richest in gold in the middle part of its course in Swiss soil.

December 7. R Wavre. Some remarks on the theory of harmonic functions The author presents three notes. a reciprocal of Green's theorem, the unity of a potential defined by its line of ramification and its period function, and the development of Poisson's integral in a series of powers of the distance from the centre, if the Fourier coefficients are taken only on an arc ψ_1 and ψ_2 from the circumference, the harmonic function given by the integral admits the two points ψ_1 and ψ_2 as points of ramification. Science and Philosophy

THERE was a blissful time when human knowledge was not formally differentiated. Without going far back into history, we may recall the wise men of ancient Greece, who never thought of drawing a distinction between mathematics and natural science, psychology and moral science So Thales and Pythagoras are hailed as the true founders of practically every major branch of knowledge Indeed, the early Greek thinkers were at the same time not only philosophers and social reformers, mathematicians and physicists, but also politicians and soldiers, engineers and traders—a fact which suggests a special conception of the unity of knowledge, if not of knowledge and action as well Even the teaching of the Academy and the Lyceum, following the Pythagorean tradition, had a universal character, though some members of these schools specialised in particular branches of learning It was not until the Alexandrians that the various sciences were really differentiated and studied separately

This unitarian conception of knowledge was developed in a most remarkable and inspiring way To take but one example, the Pythagoreans considered number not only as the basis of abstract science but also of music, ethics and religion. Such doctrines as that of the harmony of the spheres, or of the correspondence between certain numbers and the moral virtues, may appear fantastic Yet, they have a profound meaning; and strange as it may seem to be, mathematics was one of the fundamental causes which influenced the social activities of the Pythagorean order. Indeed, the discovery of the irrational quantities was the spiritual cause of the breakdown of the Brotherhood But the spirit and the method remained · it was the necessity of 'explaining' the irrationals which led Plato to build up a philosophical system in which mathematical and scientific ideas were freely used, for the justification of both Nature and the world of ideas

It was only natural that all knowledge should be one when the particular sciences were in their infancy. There is, however, a deeper meaning in the unitarian attitude of the Greek mind . it illustrates the fact that the growth of mathematical and scientific ideas is intimately interwoven with the threads of philosophy proper This attitude can be traced all through the ages up to the cosmological disquisitions of Copernicus, of Kepler, of Newton himself. Again, we find the mathematical and physical discoveries of Descartes influencing his 'method', his philosophy, his cosmology and even his biology, and suggesting to Spinoza a geometrical proof of the dictates of conscience With Leibniz we can see how the idea of the 'infinitesimally small' is made the basis not only of the calculus, but also of his conception of substance, of monads and their pre-established harmony, of psychology, ethics and theology Further, though Kant's philosophy opens with this fundamental question 'How is pure mathematics possible ?', its collapse was largely due to the discovery of non-Euclidian geometry and to the invention of imaginary quantities which could not be easily explained with that system

Kantian philosophy was, however, responsible for the definite estrangement of science and philosophy in the nineteenth century Science was firmly attached to the realm of pure reason, while the major values of reality were left to the charitable conclusions of practical reason, the arbitrariness of which ultimately cast doubts on the relevance of philosophical issues to the claims of positive knowledge. The alliance of the sciences with reason and the remarkable scientific developments of the time, led the Positivist school to discard philosophy from the sphere of human concerns With philosophy at a discount, the way was clear for a mechanist and materialist interpretation of the universe and of life The notion that to be real a thing must be of the same nature as a piece of matter, became the predominant axiom upon which was based any explanation of scientific results , and as matter can be seen and touched, whatever was real ought to be seen and touched, at least theoretically The analysis and description of a thing in terms of molecules and atoms and their movements was the sole condition of dealing with reality , all else, such as metaphysical values and religious experience, was a pointless incursion into a world of shadows Yet, it is a curious fact that the further analysis of the objects perceived finally exploded the very 'reality' they represented

This is, however, the epic of the contemporary development of our knowledge With matter considered as a hump in space-time and gradually vanishing into nothingness, the obvious and solid foundation of nineteenth century science has disappeared The imaginative conception of reality no longer being restricted by its likeness to the objects of perception, there could be no reason why the promptings of moral, æsthetic and religious experience should be still considered as unreal, and the way was thus open for a reconsideration of the philosophical interpretation of the universe on its merits The immediate effect of this new situation was to narrow the gulf between science and philosophy Physicists began to look for a solution of their particular problems in the boundless extent they discovered beyond the traditional horizon of physics In reaching out to those inquiries, philosophers became more and more interested in the methods and results of the special sciences, and brought down metaphysics into the laboratory and the market place

What are the results of this welcome cooperation ? Eminent astronomers and physicists like Eddington, Jeans, Planck and Einstein, do not conceive the world of matter as something existing independently of the mind Not only does scientific thought affect the nature of the things it studies, but also matter itself becomes simply an appearance of the mental or spiritual unity which alone is real Compared with the dogmatic pronouncement of their predecessors fifty years ago that matter alone was real, the present attitude of these scientific thinkers is its extreme opposite This complete reversion is the more arresting when one considers that matter which, in the past, was subject to the blind laws of classical mechanics, is now endowed with something almost like free-will, thanks to the implications of Heisenberg's principle of indeterminacy With Whitehead, Russell, and the idealist philosophers, this peculiar character of matter is further emphasised

The important consequences of such views in the field of biology are that life is not a by-product of blind processes of dead matter, but something fundamental and creative, exhibiting its own purposes and ends Hence arise theories of creative evolution in which the processes of life continually bring to birth something new Even those who refuse to accept a fundamental distinction between matter and life have to talk of emergent evolution, of 'organism' and of 'holism'. Whitehead, for example, considers the universe as an organic whole of which the living organism is a pattern , while Smuts assimilates biological progress with the integration of more and more elements to form larger and larger organic wholes.

When we reach psychology, however, we find the position again reversed Two generations ago, psychology was not acknowledged to be a science, on the ground that it was mainly introspective, and therefore subjective, it gave too much importance to mind as against matter, which was, as we have seen, the ultimate basis of reality To-day, however, psychology is becoming more and more objective, and with the advent of behaviourism or the conditioned reflexes, it describes the processes of the living organism in terms appropriate to a highly complicated automatic machine We are thus faced with the conclusion that freedom, which physics allows to dead matter, is refused by psychology to thinking organisms Indeed, while the highest achievement of physics is to have become subjective, the last word in psychology is to give that science an objective character

Between such extreme views, of course, a number of intermediate theories have taken their place, and though the most prominent properties of physics and biology, in the minds of some of their brilliant exponents, are their subjectivism, there are a number of physicists, biologists and philosophers who still hold mechanistic or dualistic views on the interpretation of these sciences Again, behaviourism, the doctrine of conditioned reflexes, and psycho-analysis, are not the only representatives of psychological theories idealism and dualism have still a strong following in this field This chaos of values indicates clearly that science does not tell us the whole truth about things, but only partial truths about those aspects of things which can be subjected to its methods In other words, science is not the only guide which can help us in the exploration of the universe and in the interpretation of our findings On the other hand, without the theoretical and practical data of the sciences, philosophy alone could neither undertake its scrutiny of reality, nor carry our minds to the highest flights of purposive thinking.

This mutual dependence of science and philosophy is one of the major characteristics of the intellectual atmosphere of our time Neither of them is a detachable unit in an unorganised aggregate, or an independent agent which is not itself acted upon they are both living members in the organic whole of knowledge Science and philosophy have emerged from man's contact with Nature, and have become social habits, but they are customs so geared with the world about us that they must run smoothly, irrespective of climate, race or creed. As man is a social as well as a rational animal, the vast complex of social, emotional and intellectual behaviour he has inherited from society, cannot be simply dismissed in the name of science if it cannot be described in abstract formulæ On the other hand, as science is a social outgrowth serving social ends, all attempts to isolate any aspect of it from the intellectual and social movement, of which it is an integral part, can lead to nothing but false and dangerous conclusions It is true that the scientific analysis of the universe of experience requires its division into a series of differentiated compartments, and the isolation of subjects and objects from their original context, but it would be improper and misleading to build up elaborate structures on these isolated groups, as if there were originally water-tight compartments of knowledge, each having its own independent criteria of importance On the whole, our schools and our universities seem to be designed to accentuate the practice of isolation, though the pursuit of any one thing cannot be a complete end in itself.

The reconciliation of science and philosophy we witness to-day ought to change the practical conditions of such an outlook if we believe in the constant progress of civilisation and in the greatness of human destiny An important step in the right direction would be for the academic authorities to introduce the study of philosophy and scientific method as compulsory subsidiary subjects in the official curricula for a first degree But this brings us back to the attitude of the wise men of ancient Greece, who naturally thought of human knowledge as essentially one, as against the atomised outlook of most thinkers of to-day. Whatever be the specialised fields of scientific workers, they should know how to turn to philosophy for the connecting links between their diverse interests, so as to be able to discuss with competence the true significance and value of their results On the other hand, it should be the business of philosophers not only to inquire into the higher values of life, but also to subject to a critical analysis all the presuppositions and results of science, and to build up synthetic systems of the whole realm of knowledge and experience At every new step in human progress, we find men of genius able to make synthetic attempts of this kind But while to-day science may rightly claim to have performed its part, philosophy is still in the expectation of actual systems which will provide a comprehensive explanation of the results of science and an adequate justification of the periodical and progressive changes in the material conditions and mental outlook of the human race

The Eighteenth Century Scene*

By DR ALLAN FERGUSON

WHAT is the secret of the fascination which the character of Johnson has exerted on his friends, his contemporaries, and all lovers of England for nigh on two centuries? There are no half measures about it—if you know your Johnson, you like or dislike him heartily—and the great-hearted sturdy figure has to-day, even as in his lifetime, far more friends than enemies. It is curious, too, and a reflection in some measure of his powerful personality, that his is one of the few great names in our English life and literature of whom it can be said that their reputation never suffers from the swing of the pendulum We hear little of Carlyle and Ruskin to-day; Tennyson, after suffering a temporary eclipse, is coming into his own again; following a period of obscurity, the personality and achievements of Gladstone have provided material for half a dozen recent monographs But since the day of Johnson's death the stream of comment and of criticism has never run dry. Apart from the work of the compilers of *Ana*, successive editions of Boswell by Malone, Croker, Napier, Fitzgerald, Birrell, and greatest of all, Birkbeck Hill, not to mention the misguided efforts of one or two editors to present us with a 'bowdlerised' Boswell from which the 'longueurs' have disappeared, are milestones through the nineteenth century.

Year after year sees our knowledge of Johnson now growing, now darkened by the efforts of some thesis-mongering critic who attempts to sound the depths of his complex personality with a wholly inadequate plumb and line But whatever may be our estimate of the attempts, the volume of contemporary criticism shows, eloquently enough, the interest which he provokes in any age What is at the root of it all? Let us at once anticipate the drawing-room critic by admitting the worst which can be said of him. He could be, at times, violent and overbearing, he was occasionally uncouth and absent-minded, his literary fame and greatness of mind brought small consolation to the housewife who saw her best carpet disfigured by the moralist's habit of turning his candle upside-down to make it burn more brightly, he was indolent by nature, he would argue for victory, and his temperament had a hypochondriacal and melancholy side.

All this is true enough, but it must be remembered that our critical reading is not only coloured by what we term our judgment, and our friends our prejudices, but also that the very account which we read is as much a reflection of the mentality of the writer as it is an appreciation of the figure mainly concerned. Johnson has suffered somewhat at the hands of conventional commentators, more skilled to pick out faults than to see the nobility behind them, or to realise that Johnson without his scars ceases to be Johnson. He *was* indolent; and the mass of sound work behind his name should put to shame the most industrious of his critics; he *was* overbearing and inclined to use the butt-end of the pistol in argument—as when, finding himself worsted in a discussion on the virtues of medicated baths, he cried · "Well, sir, go to Dominicetti, and get thyself fumigated, but be sure that the steam be directed to thy head, for *that* is the peccant part"

Johnson was, however, so frank in apology, so ready to take the first opportunity of reconciliation, that incidents, which loom large in the minds of critics of the feebler sort, were seen in their correct perspective by those friends who knew him far better than we can hope to do, who were competent to assess at its true value the wisdom and goodness of him who, giving small weight to conventional expressions of sympathy ("Sir . . you will find these very feeling people are not very ready to do you good. They *pay* you by *feeling*"), took on his back a poor woman of the town whom he found lying ill in the street, carried her to his house and "had her taken care of . . . till she was restored to health and . put . . . into a virtuous way of living", who not merely passively endured, but cheerfully sustained for years a nondescript household of dependents with whose queerness and bickerings Shaftesbury himself would have had small patience. He would argue for victory, and would, in the mood, stubbornly maintain a completely wrong-headed attitude Yet few men have shown in discussion such cogency of argument, such genuine humour, such force and precision of language, such aptness of illustration Could the matter be more neatly put than in his comment on the assertion that a *congé d'élire* had only the force of a recommendation? "Sir, it is such a recommendation as if I should throw you out of a two-pair of stairs window, and recommend you to fall soft". To the vague and woolly phrase and mind he was an uncompromising enemy ("Poll is a stupid slut; she was wiggle-waggle, and I never could persuade her to be categorical"). He had his melancholy fits and feared to be left in solitude. Yet none could be a gayer companion, witty and charming, welcome and at his ease in any company.

More than anything, Johnson was an amateur of life in all its phases His nature could extract a high and candid philosophy of life from keen observation of men and books, and, with one exception, he was utterly fearless, physically and morally. When, an elderly man, he was bathing with Langton and was cautioned against a dangerous pool, he thereupon swam directly into it; and—a higher virtue—he was never afraid to recognise aspects of human nature which the demands of conventionality tend to ignore A remark made by Reynolds, in Johnson's hearing, to ladies lamenting the loss of a benefactor—"You have, however, the comfort of being relieved from a burden of gratitude"—first attracted him to Reynolds; and it is an odd commentary on changing social values that this remark, recognised by Johnson in the eighteenth century as exhibiting a fair view of human nature, drew from Morley the comment that "no moralist with a reputation to lose would like to back Reynolds's remark in the nineteenth century" and is quoted by a twentieth century critic of Johnson as "the sort of thing which everyone knows to be true, but which very few venture to say".

---

* "Johnson's England an Account of the Life and Manners of his Age" Edited by Prof A S Turberville Vol. 1 Pp xxiii+405+72 plates. Vol. 2 Pp ix+404+60 plates. (Oxford Clarendon Press, London · Oxford University Press, 1933) 42s net.

No man saw more clearly the vast gulf which lies between life as it is, and life as we endeavour to cheat ourselves into believing it to be It is this clarity of vision, despite his prejudiced views on many questions of the day, which makes Johnson's writings so rich a storehouse of those compressions of thought and observation which we term aphorisms His advice to Boswell—advice applicable to weightier matters than are exhibited in the illustrations—sums up the matter: "My dear friend, clear your *mind* of cant You may *talk* as other people do You may say to a man, 'Sir, I am your most obedient-humble servant', you are *not* his most humble servant You may say, 'These are bad times; it is a melancholy thing to be reserved to such times'; you don't mind the times You tell a man, 'I am sorry you had such bad weather the last day of your journey, and were so much wet'; you don't care sixpence whether he is wet or dry You may *talk* in this manner, it is a mode of talking in Society; but don't *think* foolishly"

With this practical wisdom, goes a boyishness of spirit, and a very endearing capacity for exhibiting certain human weaknesses Witness Mrs Thrale when "I had teized him for many weeks to write a recommendatory letter of a little boy to his schoolmaster; and after he had faithfully promised to do this prodigious feat before we met again—'Do not forget dear Dick, Sir,' said I, as he went out of the coach; he turned back, stood still two minutes on the carriage step—'When I have written my letter to Dick, I may hang myself, mayn't I?'—and turned away in a very ill-humour indeed" Most reluctant performers of allotted tasks will recognise a kindred spirit here, and in that illuminating entry in the diary of his Welsh tour which records that "We then went to see a Cascade. I trudged unwillingly *and was not sorry to find it dry*".

What were the characteristics of the scene in which Johnson played so dominating a part? To obtain a faithful picture of his personality we have to realise, not only the broad outlines of the events of his times, but something of that detail—*ce superflu, si nécessaire*—so dearly loved by Austin Dobson. We know that the stage played a large part in the life of the town—we may even know something of the line of development of the eighteenth century drama; but it adds much to the vividness of the portrait if we know that the audience were seated on backless benches, which could not be booked in advance, that the system of dropping the curtain between the acts was not introduced until the mid-century; and that Garrick revolutionised the whole system of stage-lighting by substituting unobtrusive wing-lights for the chandeliers which heretofore had hung *in front* of the stage, obscuring the view, and only half-illuminating the scenery.

In the long tale of man's conquest of Nature there is no more fascinating story than that of the slow degrees by which he improved his means of communication with his fellows We know that roads were vile at the beginning of the century, and tolerable at its close—so much improved indeed that the railway at its inception had only small advantages to offer But such knowledge has little value, we need to be able to visualise the coaches, waggons and post-chaises by which our ancestors travelled and, in the spirit of Lord Kelvin's dictum that we begin to know something of a quantity when we can say how much of it there is, we find our notions of the roads of the period clarified when we realise that about the mid-century a journey of fifty miles was a good day's work, and that towards the end of the century about a hundred miles could be covered in a day. Indeed, Arthur Young remarks about 1770, "The power of expeditious travelling depopulates the kingdom Young men and women in the country villages . . . enter into service . . . to raise money enough to go into London . . . no easy matter when a stage coach was four or five days creeping a hundred miles *But now!* A country fellow, a hundred miles from London, jumps on to a coach box in the morning, and for eight or ten shillings gets to London by night; which makes a material difference" *Plus ça change*—we seem to remember similar remarks made but recently concerning the effect of the motor bus on village life.

The study of the daily habits of our ancestors provides material of never failing interest What and when they ate and drank, the type of house in which they lived, the clothes they wore, the books they read, the manner in which they farmed their land. It is so very easy to visualise the century as one of a highly artificial civilisation, an age of panniers and hoops, of affected compliments and heroic couplets, of grand tours and olympic statesmen; or, at the other extreme, as one of gaol fever, of stinking streets and ditches, of Hogarth's Gin Lane, of highwaymen, street thieves and melancholy processions to Tyburn It is perfectly true that these extreme elements form part of the picture. But a part only; and it is the province of the volumes under discussion to correct such facile and distorted views. Nowhere is this correction more effectively made than in the section which deals with town life in the provinces Many readers of to-day are apt to project their present knowledge of, say, Leeds or Birmingham, back into eighteenth century conditions, and it is with something of surprise that we learn that, outside London, the only considerable English city at the middle period of the century was Bristol with a population of a hundred thousand Norwich came next, with a population of about fifty thousand , then Manchester and Liverpool in the region of thirty thousand The populations of Hull and Sheffield were between twenty and thirty thousand, those of Nottingham, Leeds, Shrewsbury, Chester and Worcester between ten and seventeen thousand Such towns as Bolton, Bradford and Newbury were not greater in population than five thousand souls, and most of the flourishing market towns of the period were no more than large villages of two to four thousand inhabitants Their problems of lighting, paving and sanitation were not markedly different from those which face corresponding English villages to-day Perhaps their solution was not so very much lower in point of efficiency , at the moment of writing, we hear news of deaths caused by the failure of water supply in villages under the stress of the drought of 1933.

The furniture of the houses of the period is known in minute detail The topographers of the age catalogued the more striking of the contents of the mansions of the nobility and gentry, and legal inventories and auctioneers' catalogues are not unknown One striking feature of the interior furnishings of the period is the small part which the bath and the bathroom play therein Johnson himself remarked to the Lichfield draper showing him his cold bath, "I hate immersion", admonishing him to "let well alone, and be content" , and we are told of the eleventh Duke of Norfolk that he was "never thoroughly washed except when he was so drunk that his servants were able to place him in his bath without his being sensible of it".

The section which deals with the house interior is remarkably full in its account of the furniture of upper class houses. Beautiful examples of period furniture are described and illustrated, but we would willingly have sacrificed some of this in order to obtain more knowledge of farms, cottages, alehouses and the village inn with

"The whitewashed wall, the nicely sanded floor,
The varnished clock that clicked behind the door,
The chest contrived a double debt to pay,
A bed by night, a chest of drawers by day ,
The pictures placed for ornament and use,
The twelve good rules, the royal game of goose,
The hearth, except when winter chilled the day,
With aspen boughs, and flowers and fennel gay ,
While broken teacups, wisely kept for show,
Ranged o'er the chimney, glistened in a row"

The paucity of this information is not fully compensated by an extract from Southey descriptive of an early nineteenth century farmhouse, or a brief description of the plates of "*Marriage à la mode*" One inventory which has escaped the author's notice—a catalogue of very deep interest to the readers of NATURE—is that which describes the contents of the house in the parish of St. Martin's-in-the-Fields, in which Sir Isaac Newton died Newton died intestate and, as was discovered by Lieut -Col. de Villamil, a very detailed inventory of the contents of his house was taken at the instance of the Prerogative Court of Canterbury. The records of this court are preserved at Somerset House, and a close search revealed the inventory in the form of a vellum roll some five inches broad and seventeen feet long The detail is remarkable, so much so that it would not be a difficult matter to refurnish every room in a reproduction of Newton's house in the exact style in which he lived The inventory would seem to fill a gap in the literature , it gives a very complete picture of a middle class house in the year 1727. Here again, despite an astonishing particularity of description which includes certain articles of bedroom furniture in silver, and descends to a tabulation of "a leaf of a table two old coats two old hatts a pair of tongs a perriwig block two leaden flower pots" in the stable, the only mention of a bath is found in the inventory of the "fore room two pair of stairs", where we read of "three globes a copper plate a silver watch a Bath mettle case of instruments a shagreen case Do a small penknife an embroidered purse two plaistered heads and two small pictures". We fear that the word *Bath* here refers to the alloy (three or four ounces of zinc to a pound of copper) of which the case is composed

It would be an impossible task to summarise adequately the contents of the twenty-seven sections of these volumes—sections which cover almost all of the activities of the age, and furnish us with a picture, most skilfully conceived and carried out, in which the immense detail necessary for any accurate scholarship is introduced into the main structure in so thoroughly interesting a fashion that its presence is never felt to be overwhelming, nor permitted to obscure the main outlines. We have seen that daily life and habits in the metropolis and in the provinces are adequately treated. The Church, the Army, the Navy, trade and rural life, travel and discovery, sports and costume, all find representation We are introduced to a study of the law of the period, a mass of queer, interesting and archaic technicalities wherein, for example, under a writ of debt, a defendant could wage his law, that is, could "swear that he did not owe the money . . and produce eleven compurgators to swear that they believed him" , and the defendant could escape scot free if he managed to find eleven such hard swearers ! True, the lawyers had discovered subtle ways to make the process difficult, but so late as 1824 such a case occurred, and the possibility was not finally disposed of until the Act of 1833.

The arts of painting, engraving, sculpture, architecture, the drama and music have each a section devoted to them, and three very important divisions deal respectively with medicine, education and science. The last-named section gives, as is natural, much of its space to the story of phlogiston and to the discovery and manipulation of gases Sections on authors and booksellers and on the newspaper close a study which provides material of most absorbing interest, and which may fairly be called indispensable to a student of the period. It will none the less prove attractive to the general reader and will receive an unstinted welcome from all sound Johnsonians We hope that Prof Turberville will continue the good work —a study of Tennyson's England covers almost the same period in the nineteenth century that is covered in the eighteenth by the present study, and it has its possibilities

Manufacture of Sheet and Plate Glass

IN a Friday evening discourse delivered at the Royal Institution on December 8, Major R M Weeks, of Messrs. Pilkington Brothers, Ltd, described, and illustrated by lantern slides and films, the methods in use for the manufacture of sheet and plate glass

The principal raw materials used in the manufacture of sheet and plate glass are sand, soda ash and limestone These materials, perhaps with the addition of arsenic, anthracite, alumina or magnesium carbonate, all in a finely divided condition, are intimately mixed prior to melting. There are two well-known processes for melting this mixture (1) The older method, in which the materials are melted in clay pots, and a definite time-temperature schedule is allotted to melting, founding, refining and cooling off to the working temperature As many as twenty melting pots are sometimes accommodated in one furnace (2) The more modern method, in which the mixed raw materials are fed on at one end of a tank furnace where they are melted The molten glass then flows through controlled temperature zones which ensure the founding and refining, and finally arrive at the working end at the required temperature Such tanks contain anything up to 900 tons, and the temperatures may vary from 1450° to 1200° C in different zones

Sheet glass was first made by a blowing and spinning process Such glass, known as 'crown glass', was characterised by the 'bull's eye' in the middle of each disc This method was followed in 1832 by the 'blown' process, in which the gathering of glass was blown into the form of an elongated cylinder After separating the cylinder from the blowing iron, the ends were cut off, and the cylinder split down its length and flattened into a sheet. In 1909, a mechanical method of drawing cylinders of a larger size was introduced from the United States By this method, cylinders 40 ft. long and about 3 ft. in diameter are drawn (Fig. 1) Such cylinders are cut up into sections before flattening and annealing

Since 1900, three processes for the drawing of flat sheet glass have been developed commercially: (a) Fourcault process, (b) Colburn or Libbey-Owens, and (c) Pittsburg process. In the Fourcault process, glass is drawn as a sheet vertically from a slot in a depressed fireclay float. In its early days, devitrification was a source of trouble. In the Libbey-Owens process the sheet is drawn from an open bath of molten glass, and thus excessive devitrification troubles are avoided, but the sheet when formed is reheated and bent to the horizontal by being passed over a bending roller The Pittsburg process is a modification of the Fourcault process, the chief difference lying in the use of a bar of fireclay submerged beneath the surface of the glass to define the position of generation of the sheet

FIG 1 Drawing sheet glass cylinders mechanically

The making of plate glass involves two distinct processes · (1) manufacture of rough glass blanks; and (2) grinding and polishing of these blanks. Since 1774, plate glass blanks have been cast from glass melted in pots Typical melting pots contain about a ton of glass and yield plates of about 300 square feet, at a thickness of 7/16 of an inch. The casting consists in taking the pot from the furnace and pouring the molten glass on to a smooth iron table in front of a roller. The rolled blank is then annealed, a process which in earlier times occupied three days, but now, for a blank ½ in. thick, occupies 2¼ hours

A modern modification of this process, due to Bicheroux, consists in pouring the molten glass between two rollers on to a moving table (Fig 2) The irregular beginning and end of the sheet are cut off while still hot by a guillotine and the trimmed sheet is then passed into an annealing lehr, from which it later emerges ready for cutting and polishing This process gives a smoother and flatter sheet than the older single roller process consequently, there is less loss of material and reduced time required for the grinding process.

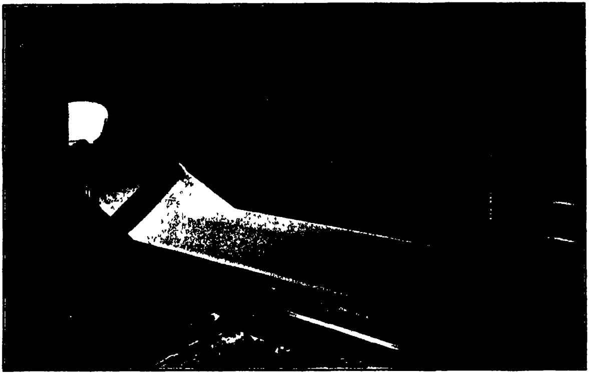

FIG 2 Casting plate glass blanks by the Bicheroux process

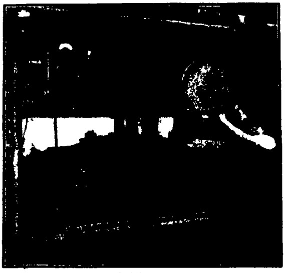

FIG 3. Polishing plate glass

The most modern process of all is a modification of the Bicheroux process, and consists in the continuous discharge of a stream of glass from a tank furnace between a pair of forming rolls, from which it issues in the form of a continuous ribbon or sheet, which passes over a roller bed and through an annealing lehr

In the second stage of the process of preparing plate glass, namely, grinding and polishing, the grinding is accomplished by using progressively finer grades of sand fed with water, under cast iron runners This is continued until a frosted surface of the finest possible texture is obtained The polishing process is then begun and consists in rubbing the glass with felt discs fed with carefully prepared rouge (Fig 3) All plate glass used to be, and much still is, ground and polished on rotating tables on which the glass is embedded, but this method has been superseded by a continuous process.

Machines used in this continuous grinding and polishing process are very large and expensive units; some are so much as 800 ft long by 15 ft. wide.

Two recent developments of note in flat glass manufacture are (1) coloured opaque glass known as "Vitrolite" and (2) toughened plate glass known as "Armourplate". The latter is made by the suitable heat treatment of ordinary plate glass

S. E.

Obituary

PROF FRITZ HABER

BY Fritz Haber's death, chemistry loses one of its outstanding personalities He was one of the greatest of academic chemists, of industrial chemists, and of leaders of research, while in his combination of these three rôles he was unique , at the same time he remained the most unaffected and kindest of men

Haber was born in Breslau on December 9, 1868 His early education as a chemist was unusual, and indeed, as he would often say, he was as nearly as possible a self-made man of science He attended courses in Berlin, Heidelberg, Charlottenburg, Zurich and Jena , he worked under Hofmann, Helmholtz, Liebermann (with whom he published his first paper on some derivatives of piperonal), Lunge and Ludwig Knorr, yet he never obtained from their courses the satisfaction which he desired As a young man he spent some months in various industrial works , he was even for a time in his father's office before he returned finally to science When he was twenty-six years old, he obtained a post as assistant to Bunte in the Institute of Chemical Technology at Karlsruhe, where his real work began, and where he remained for seventeen years

At Karlsruhe, Carl Engler and Bunte encouraged him to develop his own school of research Though Haber had received no formal instruction in physical chemistry, it was in this field that his main interests lay, and in a few years papers were appearing under his name on the combustion of hydrocarbons, the water-gas equilibrium in the Bunsen flame, and aspects of textile chemistry , but above all his main interests lay in the field of electro-chemistry His classical studies on electrolytic oxidation and reduction belong to this period , these began with his demonstration of the stages of the reduction of nitrobenzene (1898) This was followed by work on the electrolysis of solid salts (1904), on the glass electrode, on the velocities of electrode processes (1902–8) and on gas and carbon cells, all work showing him at the height of his powers Throughout the same time he was also engaged on his classical work "Thermodynamics of Technical Gas Reactions" (1905) His laboratory was filled with students from all parts of the world , unhampered by administrative cares, it was the most productive phase of his career

To this period also belongs the beginning of Haber's work on the synthesis of ammonia from its elements, work which led to the discovery of one of the most important of all industrial processes. His first paper on the equilibrium constants of this reaction appeared with Van Ordt in 1904, and in 1906, with Le Rossignol, he undertook a repetition of the measurements, over a much wider range of temperature and pressure It was then apparent that a catalyst which would operate satisfactorily at 600° C would make this process possible industrially, and to a man of Haber's breadth of vision the significance of the fact must have been immediately obvious An unremitting search was made for such a catalyst, and uranium and osmium were found to be effective A small technical high-pressure apparatus was constructed, and in June of 1908 two directors of the Badische Anilin- und Soda-Fabrik were invited to Karlsruhe to witness the first demonstration of the model at work After an initial failure, liquid ammonia was produced, and a process of enormous importance to Germany and to the world was launched Bosch and Mittasch undertook the task of converting the model into a full-scale plant, and with the constant shrewd co-operation of Haber the process was ultimately brought to the highest pitch of efficiency Haber received the 1918 Nobel prize for chemistry for this work

In 1906, at the age of thirty-eight years, Haber succeeded to Engler's chair, but left five years later to undertake the direction of the newly founded Kaiser Wilhelm Institut fur physikalische Chemie und Elektrochemie at Berlin-Dahlem Under his guidance this became the greatest research institution of its kind in the world , groups of research workers were left with the fullest freedom to develop their own ideas, while Haber gathered around him a devoted and talented staff whom he provided with every material and moral facility for the unhindered progress of their work No man ever had a more devoted band of colleagues, and no man ever spoke of them more appreciatively than he did

Haber's interest in the applications of the newer physics to chemistry was reflected in many papers at this time His work with Just, on the emission of electrons during chemical reaction, had been published from Karlsruhe , and after the War he continued in the same vein with his pioneer work on the physical meaning of chemi-luminescence, and on the applications of the methods of spectroscopy to the analysis of the processes of combustion

At the outbreak of the War, Haber was impressed by Germany's need for expert organisation of all her industrial resources He offered his services to the Prussian War Ministry, where he was soon installed as head of the Chemical Warfare Department There he worked unremittingly throughout the War. His advice and personal service were constantly in demand from all quarters, and such were his unrivalled knowledge and sanity of judgment that his name at this period became almost legendary throughout the country. He never sought to disclaim the responsibility for the use of poison gas, which was indeed the direct concern of his Department, but it should be remembered that latterly he gave up much of his time to serving on the League of Nations Committee on Chemical Warfare

The War years left him with shattered health, faced with the difficulties of reorganising an institution the funds of which were already dwindling owing to the monetary inflation, but with the secure conviction that only by the encouragement of research could German industry hope to regain its former position in the world. He played a leading part in the foundation of the Notgemeinschaft der deutschen Wissenschaft, and though some of his plans for the expansion of the Kaiser Wilhelm Institut had to be abandoned, it was not long before it was again in the forefront of research organisations. Meanwhile he himself was organising an attempt to pay the German War debt in gold won from sea-water, an attempt which failed yet yielded scientific results of importance.

The last years at Dahlem brought cares in plenty, but Haber's many industrial and administrative troubles were never allowed to interfere with the output of research from his private laboratory. The greater part of his work now was concerned with chain reactions and the mechanism of oxidation; perhaps his early association with Engler was responsible for this, and on this subject he worked with his assistants until the time of his death. He remained what he had always been, the ideal director of research, approachable, interested in everything, but above all the leader of the work of his Institute. His health was bad, but his industry enormous. Two honours he much appreciated were his election as an honorary fellow of the Chemical Society in 1931, and the award of the Rumford medal of the Royal Society in 1932.

The political situation in the spring of 1933 led to Haber's resignation. Almost all his staff and pupils were forced to look elsewhere for opportunities to continue their work, and he gave up his post rather than remain at Dahlem without them, in a country the political temper of which was so foreign to his own liberality of outlook. He spent himself unsparingly in helping his assistants and colleagues to find opportunities for continuing their work, and ultimately himself accepted an invitation of laboratory hospitality at Cambridge. He went to Cambridge in October and remained there to within a few days of his death. He had left for a short holiday on account of his health, intending to return to reside permanently at that University; but he died during the journey, at Basle, on January 29, 1934.

Haber was equally outstanding as a man and as a chemist. His amazing knowledge of politics, history and economics, as well as of science and industry, and his superb gift of expression made him a fascinating conversationalist. It was always a joy to hear him tell a story, whether it was an anecdote of the War or one of his famous medieval romances. After a paper or a colloquium he showed his powers at their fullest. Never at a loss, whatever the subject, he would always open the discussion with some characteristic contribution of his own, in a way which showed his complete grasp of the subject. One of his outstanding characteristics was his pride in his work; the final preparation of a paper was a work of infinite labour, but once it was completed he found it hard to accept any alteration in its conclusions; and though he was quick to acknowledge any mistake it was a source to him of acute mental discomfort. To his pupils he remained always courteous and affectionate, and to them his death is a great personal loss; but the world also is the poorer by the loss of one of its great benefactors and one of its great men.

O. H. W.-J.

DR. F. L. KITCHIN, F.R.S.

DR. FINLAY LORIMER KITCHIN was appointed palæontologist to the Geological Survey of Great Britain in 1905. He was attacked by sudden illness on January 17, 1934, and died in St. Thomas's Hospital on January 20. The post which he held for nearly thirty years was one which required an accurate and wide knowledge of the whole field of palæontological science, and he filled it with distinction and marked success. As a successor to such eminent men of science as Huxley, Salter, Etheridge, Shannon and Newton, he recognised the necessity of maintaining a high standard of performance and in no respect did his endeavours sink below the level of his predecessors.

Devoted to his subject, Kitchin was meticulously accurate, and at the same time he was able to co-operate freely not only with his official assistants but also with academic and other palæontologists who sought his advice. Being in charge of one of the largest collections of British fossils, on the curation and growth of which he had spent a large part of his working life, he acquired an experience of British stratigraphical palæontology which was probably unique. But he spared no efforts to secure the most accurate determinations, and he grudged neither time nor trouble, though often working on material which had less morphological value than stratigraphical interest. In this respect the value of his services to British geologists working in the field was unprecedented.

Kitchin's special sphere of work was in the province of Mesozoic palæontology. His earliest thesis, for the degree of Ph.D. at the University of Munich, where he studied under Zittel, was on Indian Jurassic Brachiopoda, and among his most important contributions to British palæontological stratigraphy were the two memoirs which he wrote with Dr. John Pringle on the Mesozoic rocks penetrated by borings in the coalfield of Kent. He also investigated the stratigraphy of the British Gault and contiguous formations, on which he wrote a number of useful papers. But he was very largely occupied by the preparation and editing of the palæontological chapters of memoirs on British geology, and the value of his services in this direction cannot be measured in terms of the amount of output which can now be attributed to his name.

For thirty years Kitchin held a leading place in the esteem of all his fellow workers, and his thoroughness and critical ability gained the confidence not only of his colleagues but also of all stratigraphical palæontologists both in Britain and abroad

Dr Kitchin was born in Whitehaven in 1870 and educated at St Bees School and at St John's College, Cambridge. After graduating at Cambridge he studied at Munich for several years For a short period he worked unofficially at the British Museum, and in 1898 he joined the Geological Survey as an assistant to E. T Newton He became palæontologist in 1905 He was a vice-president of the Palæontographical Society and a fellow of the Royal Society He took the degree of Sc D at Cambridge in 1923 For many years he had served on the council of the Geological Society, which in 1934 awarded to him the Lyell Medal, an honour which he did not live to receive

Dr. Kitchin had a very wide circle of friends who were attracted to him by his obvious sincerity and great willingness to help all earnest scientific workers. Of a retiring disposition, he was passionately fond of music and was himself no mean executant He was twice married and leaves a widow, two sons and one daughter On January 23, at Golder's Green, a large assembly of colleagues and scientific friends paid their last respects to a man of science, who was not only personally beloved, but had also taken an important part in the scientific activities of British palæontologists for nearly forty years J S F.

MR DOUGLAS W FRESHFIELD, D C L

MR DOUGLAS FRESHFIELD, who died in his eighty-ninth year on February 9, was prominent as a promoter of the serious study of geography for more than fifty years As an Eton boy he made several ascents in the Alps and his love of mountains grew with his growth He was recognised as one of the greatest mountaineers of the Alpine Club, but his attitude was that of an explorer and student of mountains rather than that of a sportsman, keen on records of first ascents He broke new ground in the Alps, the Caucasus and the Himalayas, and in his sixtieth year he started from Mombasa with the intention of making an ascent of Mt Ruwenzori, and he reached 12,000 ft before turning He wrote many books of much charm, the two largest, "The Exploration of the Central Caucasus" (1896) and "Round Kangchenjunga" (1903), are permanent works of great value, masterpieces of the literature of travel and illustrated with superb photographs His biography of the great Swiss mountaineer and man of science, H. B de Saussure (1920), was recognised as a classic

Mr Freshfield was admitted a fellow of the Royal Geographical Society in 1869 by Sir Roderick Murchison, and became a member of the council in 1878. Except for the ten years following 1894, when he withdrew from the affairs of the Society as a protest against certain retrograde tendencies, he served throughout his life as honorary secretary, vice-president, president (during the difficult War years 1914–17) and finally in the high office of trustee He was always a force for progress and in continuous opposition to the tyranny of old tradition His reserved nature and fine taste led him to shun publicity, but when the occasion demanded it, as in the fight for the admission of ladies as fellows in 1893, he took a prominent part and conducted controversy with cogent argument and caustic wit

Freshfield made no pretence of being a scientific man, but he preached and practised the doctrine of acute observation and accurate description. He rendered noble service to the science of geography by his encouragement of research and of higher education In 1884, recognising the futility of the Society's scheme of encouraging geographical education by offering prizes to the public schools, he initiated an inquiry into the state of geographical teaching on the Continent and secured the appointment of the late Sir John Keltie for that purpose The resulting report started the modern revival in British geography Mr Freshfield continued to urge that the best way to improve school teaching of the subject was to secure the recognition of the high cultural value of geography by the universities Starting with his own University of Oxford, he secured the appointment of Sir Halford Mackinder as reader in geography in 1887 when there was no chair of geography in any British university, and he lived to see professors and honours schools of geography in practically every one as the direct result of his initiative

For thirteen years Mr. Freshfield acted as president of the Geographical Association, the activity of which in its special province of education he watched over with an interest only exceeded by his devotion to the work of the Royal Geographical Society and of the Alpine Club

Freshfield's life was a fine illustration of the tradition of service which has led so many men of wealth and culture in England to toil for great ideals as strenuously as most men have to work for their living HUGH ROBERT MILL

WE regret to announce the following deaths

Mr E G B Meade-Waldo, an original member of the Society for the Protection of the Fauna of the Empire, on February 24, aged seventy-nine years.

Dr F C Purser, president of the Royal College of Physicians of Ireland and professor of medicine in the University of Dublin, on February 28

Mr William Barlow, F R S, known for his early work on the relation of crystal structure to chemical composition, on February 28, aged eighty-eight years.

Prof. S. F. Oldenburg, for twenty-five years permanent secretary of the Russian Academy of Sciences, on February 28, aged seventy years

News and Views

New Fellows of the Royal Society

THE following have been selected by the Council for election to the fellowship of the Royal Society :— Mr A S Besicovitch, Cayley lecturer in mathematics, University of Cambridge, Prof W E Curtis, professor of physics, Armstrong College, Newcastle-on-Tyne, Dr L L Fermor, director of the Geological Survey of India, Dr Paul Fildes, research bacteriologist, London Hospital; Dr R T Grant, lecturer in cardiac pathology, University College Hospital Medical School, London, Mr M A. C Hinton, deputy keeper of zoology, British Museum (Natural History), Dr. E L. Hirst, senior lecturer in organic chemistry, University of Birmingham, Dr E L Kennaway, director of the research laboratory, Cancer Hospital, London, Mr A G M Mitchell, consulting engineer, Melbourne, Prof W A Parks, professor of geology and head of Geology Department, University of Toronto, Prof H Raistrick, professor of biochemistry, University of London, Prof A O Rankine, professor of physics, Imperial College of Science, London, Lieut -Col R B Seymour Sewell, leader of the John Murray Expedition to the Arabian Sea, and director in 1925-33 of the Zoological Survey of India, Calcutta, Prof S. Sugden, professor of physical chemistry, Birkbeck College, London, Mr William Taylor, mechanical engineer, managing director of Messrs Taylor, Taylor and Hobson Ltd, Leicester, Dr H Hamshaw Thomas, University lecturer in botany, University of Cambridge, Rev Alfred Young, mathematician, rector of Birdbrook, Essex

New Fellows of the Royal Society of Edinburgh

AT the ordinary meeting of the Royal Society of Edinburgh, held on March 5, H R H the Duke of York was elected an honorary fellow The following ordinary fellows were also elected Dr D Bain, lecturer in technical chemistry, University of Edinburgh, Dr P Brough, lecturer in botany, University of Sydney, Prof I de Burgh Daly, department of physiology, University of Edinburgh, Dr F F Darling, chief officer of the Imperial Bureau of Animal Genetics, University of Edinburgh; Prof D R Dow, Department of Anatomy, University of St Andrews (University College, Dundee), Mr W L Edge, lecturer in mathematics, University of Edinburgh, Dr I M. H Etherington, lecturer in mathematics, University of Edinburgh, Mr G Fraser, chartered civil engineer, Prof J Glaister, Department of Forensic Medicine, University of Glasgow, Dr. R. M. Gorrie, Forest Research Institute, Dehra Dun, U.P, India, Mr D Haldane, senior geologist, H M. Geological Survey (Scotland), Edinburgh, Dr J V Harrison, geologist, Glasgow; Mr J Jeffrey, Under-Secretary of State for Scotland, Edinburgh, Sir William Johnston, Deputy Keeper of the Signet, Dr R. Cranston Low, formerly lecturer in dermatology, University of Edinburgh, Brigadier General Magnus Mowat, secretary of the Institution of Mechanical Engineers, London, Mr. W G R Murray, technical assistant, Department of Chemistry, University of Edinburgh, Prof A R Normand, Department of Chemistry, Wilson College, Bombay; Prof R K Pal, Department of Physiology, Prince of Wales Medical College, Patna, India, Dr H J Plenderleith, Research Laboratory, British Museum, London, Dr D E Rutherford, Carnegie Teaching Fellow in mathematics, United College, University of St Andrews; Capt H K Salvesen, shipowner, Edinburgh, formerly fellow of New College, Oxford, 1923-28, and lecturer in economics, Dr M S. Thomson, physician for diseases of the skin, King's College Hospital, Belgrave Hospital for Children, London Dr. J Weir, lecturer in palæontology, University of Glasgow, Mr W Whyte, cashier and general manager, Royal Bank of Scotland, Edinburgh, Dr W P D Wightman, science master, Edinburgh Academy, Prof B M Wilson, Department of Mathematics, University of St Andrews (University College, Dundee); Dr A Winstanley, engineer to Safety in Mines Research Board, Edinburgh

Sir James Jeans. President of the British Association

ON account of the lamented death of Sir William Hardy, it became necessary to elect a new president of the British Association for the meeting to be held at Aberdeen in September next The General Committee of the Association, which met for this purpose on Friday, March 2, elected Sir James Jeans to this office, and we understand that he has accepted the invitation to serve It is scarcely too much to say that no man of science now living is better known than he is to intelligent readers—both scientific and lay—through his brilliant expositions of complicated physical and mathematical conceptions These rare qualities have enabled him to open new realms of thought and inquiry to philosophers as well as experimentalists, and also to interest laymen in the development of ideas relating to the universe These involve explanations of relativity, quantum and wave mechanics and other novel aspects of cosmogony with their philosophical implications In literary style and scientific substance these works are among the best of their type ever produced, and their widespread circulation is a gratifying sign of public interest in intricate scientific subjects when made intelligible by artistic expression. What renders Sir James Jeans unique, however, is that he should possess this gift and at the same time be a leading authority in the field of mathematical physics and the author of those substantial contributions to the dynamical theory of gases and the mathematical theory of electricity and magnetism and dynamical astronomy, which led to his election into the Royal Society in 1906 and the award of a Royal medal in 1919. We may confidently anticipate that his presidential address to the British Association will enrich the literature of science and be worthy of the intellectual outlook of the great university and city in which it will be delivered.

Dr. H Moore

DR HAROLD MOORE, who has just taken office as president of the Institute of Metals, was born in 1878, and began his metallurgical career as a pupil of the late Dr. J E Stead In 1901 he became research metallurgist at the Parkhead steel works of William Beardmore and Co , Ltd., where his work in connexion with the manufacture and heat-treatment of armour-plate developed his interest in alloy steels Rapid progress was then being made in the application of nickel-chromium steels for this and other purposes Later work has shown that some of the methods of heat-treatment then developed empirically must have had the effect of suppressing temper brittleness, a trouble that was not clearly defined until some years later In 1904 Dr. Moore joined, as chief metallurgist, the Research Department at Woolwich Arsenal, where he remained for twenty-eight years, from 1919 until 1932, being director of metallurgical research As chief metallurgical adviser for many years to the War Office and the Ordnance Department of the Admiralty, Dr Moore had a wide experience of Service problems both on the manufacturing and the applications sides In 1922 a research on the casting of brass ingots was undertaken under his direction for the British Non Ferrous Metals Research Association, and this led to a gradually increasing co-operation between the Association and the Research Department, Woolwich, which undertook work on lead cable sheathing (in the course of which the widely used B N F ternary alloys of lead were developed), electrodeposition of nickel, tin coatings, etc In 1932 Dr Moore accepted the offer of the post of director of the British Non-Ferrous Metals Research Association, which had become vacant through the election of Dr R S Hutton as Goldsmith's professor of metallurgy in the University of Cambridge

Prof. William Buckland, 1784-1856

MARCH 12 marks the one hundred and fiftieth anniversary of the birth of the Rev William Buckland, geologist and father of the famous naturalist, Frank Buckland William Buckland was born at Tiverton, Devonshire, on March 12, 1784 He went up to Corpus Christi College, Oxford, from Winchester in 1801 and was elected a fellow of his College in 1808 Five years later he was appointed Oxford reader in mineralogy and was elected a fellow of the Geological Society, of which body he was twice president He was elected a fellow of the Royal Society in 1818, in which year he was appointed first professor of geology at Oxford. Upon the discovery of the Kirkdale Cave, Pickering, Yorkshire, in 1821, in which the fossil bones of numerous Tertiary animals were found, Buckland made a careful examination, and in 1822 the Royal Society awarded him its Copley medal for his account of the study of the remains found in the cave In 1823 he supplemented his observations on Kirkdale Cave by publishing "Reliquiæ Diluvianæ". A century ago he was working at his well-known Bridgewater Treatise (awarded for an essay "On the power, wisdom, and goodness of God, as manifested in the creation"), "Geology and Mineralogy considered with reference to Natural Theology", which was published in 1836 After his appointment as Canon of Christ Church in 1825, he lived at the House for twenty years, and it was in a wall in the Canon's garden that he tested the power of toads to live when immured in rock cavities In 1845 he was made Dean of Westminster. The strain of his new work at Westminster undoubtedly shortened his life, and he died and was buried at Islip in August 1856

Research on Influenza

THE extermination of the polecat in Great Britain was carried out with deplorable success in the eighteenth and early nineteenth centuries It is fortunate for the progress of knowledge that it survived in the domesticated form of the ferret, which was of immense service in solving the problem of the cause and prevention of dog distemper, and now promises to be of equal value in studying human influenza The facts so far ascertained at the National Institute for Medical Research at Hampstead are not conclusive but they are certainly very suggestive Dr P P Laidlaw, Dr C H Andrewes and Dr W Smith have found that washings from the noses of human cases of influenza, after passing through a bacteria proof filter, cause a characteristic febrile and catarrhal attack when instilled into the noses of ferrets, which by similar means can be carried on to other ferrets in series No other animal which has been tried is susceptible in the same way, and no other method of inoculation will infect the ferret—so much does progress rest on technique Recovered ferrets are immune and their blood will neutralise the infective material, as will the blood of human beings who have passed through an attack The facts fit in well with the idea that uncomplicated human influenza is relatively a trivial disease and that when the cyclical epidemics fall in the summer months they attract no great attention if they come in the winter they give a severe affection with a substantial mortality due to the secondary invasion of the lungs by Pfeiffer's bacillus, streptococci and perhaps pneumococci In the 'influenza' of pigs studied by Shope in America, the virus causing the primary disease is of practical importance only because it allows infection by the secondary bacillus

Petrol from Coal

THE liquid products of the carbonisation of coal at low temperatures have been disappointing because they lack the chemical characteristics which give special value to high temperature products Thus, low temperature tar oils have had to be used as boiler fuel oils—which is the lowest use to which a manufactured oil can be put It is, however, satisfactory to know that the Admiralty has been able to use such oils as fuel and thus satisfy its needs from British coal Researches now proceeding may provide new outlets for low temperature oils. As a source of motor spirit, low temperature products are also at a disadvantage, the crude spirit being troublesome to refine owing to a high proportion of unsaturated compounds liable to form gums on the engine. Moreover, the spirit, when refined, lacks the aromatic compounds which give to benzole its high 'anti-knock' value. The necessity for removing the unsaturated compounds is regrettable because they also possess 'anti-knock' qualities. Modern methods of refining benzole permit the retention of the unsaturated compounds while inhibiting their tendency to form gums. It is noteworthy that the spirit produced in the manufacture of coalite has given such satisfaction in use by a squadron of the Royal Air Force that, according to the *Times* of March 1, the Air Ministry has awarded a new contract for this spirit to cover the requirements of seven squadrons.

24-Hour Time System

WE are glad that the subject of the 24-hour system of time reckoning has again been raised in the House of Commons. In a written reply on March 5 to a question asked by Sir Arnold Wilson, the Postmaster-General stated: 'I understand that the British Broadcasting Corporation intend at an early date to adopt the 24-hour system of expressing time for general use and on an experimental basis. This will afford an opportunity for testing the attitude of public opinion, and I propose therefore to await the result of the experiment before coming to a decision."

University of Durham

THE Prime Minister announced in the House of Commons on March 6 that a Royal Commission has been appointed to inquire into the affairs of the University of Durham and its constituent colleges. Its terms of reference are :—"To inquire into the organization and work of the University and its three constituent colleges and into the relation of the University to those colleges, and to report in what respects the present organization can be improved and what changes, if any, are desirable in the constitutions, functions, and powers of the University and its three constituent colleges." The members of the Commission are Lord Moyne (chairman), Countess Grey, Sir Ross Barker, Major A. G. Church, Dr. H. R. Dean, the Rev. F. Homes Dudden, Dr. T. F. Sibly, and Mr. W. Spens.

Research in Engineering

IN his Friday evening discourse delivered at the Royal Institution on March 2, on "Some Current Research Problems in Engineering", Dr. H. J. Gough, superintendent of the Engineering Department of the National Physical Laboratory, described the main group of researches in progress in his department. As representative examples, researches on wind pressure on structures, impact forces between vehicles and the road and failure of metals in relation to crystalline structure were discussed and demonstrated. An investigation of the wind pressures acting on a shed, 100 ft. by 42 ft. by 33 ft., was described, air flow conditions being rendered visible by using a small wind tunnel and models of buildings in conjunction with an optical system employing the *Schlieren* method. An interesting feature of the investigation was the existence of dangerous suction effects tending to lift off roofs and suck out leeward walls. The importance in engineering service of the particularly dangerous and insidious type of failure known as 'fatigue' was discussed; the problem is also one of considerable scientific interest as it affords a convenient line of attack upon the general problem of the cohesion of matter. The use of large metallic single crystals has opened up a new field of study on both the practical and scientific aspects of fatigue. Fatigue in ductile metals is closely bound up with the effects of plastic distortion, or 'slip', upon the crystalline structure of these metals. The normal form of metals—consisting of crystals of varying orientations each composed of definite arrangements of atoms—was briefly described and the general and particular mechanisms of slip were demonstrated, employing lattice and other models. The effect of slip upon the actual crystalline structure, as deduced from X-ray data, was discussed, reference being made to 'crystal break-up' and lattice distortion, in relation to hardening. A tentative explanation of the cause and location of the initiation of fatigue cracks was described.

IN addition to the demonstrations given during Dr. Gough's discourse, exhibits relating to other researches in progress in the Engineering Department of the National Physical Laboratory were on view in the Royal Institution Library. The effect of the conditions of the surface on such engineering components as wrought iron chain, springs for vehicles, etc., is often of considerable influence on the resistance to impact loading or to repeated cyclical loading. In investigating the latter effect, a machine for applying cycles of torsional stresses was shown at work; this machine also demonstrates that quasi-elasticity is exhibited by materials even when subjected to repetitions of a range of stress which will *not* lead to fracture. Characteristic examples of fatigue failure in engineering service were exhibited, and the first high speed machine for investigating the behaviour of metals under combined fatigue stresses was shown in operation. Another machine demonstrated the characteristics of film lubrication between surfaces undergoing relative reciprocating motion; the coefficient of friction is independent of load but varies with speed and temperature, hence the friction is not of the true boundary type but relates to a thicker film. The skidding characteristics of road vehicles were demonstrated by models showing that: (*a*) with locked rear wheels the vehicle turns round while, if the front wheels are locked, the path of the vehicle is straight; (*b*) the turning effect arising from locked back wheels is caused by lack of directional control at the rear of the vehicle; (*c*) 'steering into the skid' tends to preserve a straight path; also, that over-correcting or delay leads to a series of swerves; (*d*) equal breaking on all four wheels can result in rotation of the vehicle and may be dangerous.

Elements Old and New

THE historical development of the conceptions of 'atom' and 'element' were outlined by Prof. James

Kendall, professor of chemistry in the University of Edinburgh, in delivering the twenty-fifth Bedson lecture in Newcastle-upon-Tyne on March 2. He pointed out that there have been four great periods of chemical discovery, corresponding quaintly with the four 'elements' of the Greeks, fire, air, earth, and water. The first was the phlogistic period, ending with Lavoisier; the second, the great period of research on gases; the third, the gradual rounding off of the chemistry of the rare earths; and the last opened up by the discovery of heavy water. It was mentioned that there should be nine kinds of water, and more than a hundred varieties of ethyl alcohol "some perhaps more exhilarating". Of great interest was the account of a research just concluded in the Edinburgh laboratories in which calcium from a mineral rich in potassium has been shown to have a slightly higher atomic weight owing to the isotope derived from the radioactive isotope of potassium, K^{41}. *This has been confirmed by Allison in the* United States, using his magneto-optic method. Two pegmatites of very different ages, but of which the younger contains much less calcium than the older, have indicated a half life period of 9×10^{11} years for potassium in agreement with one of two measurements by direct physical methods. The lecture was enlivened by numerous amusing reminiscences and suggestions, especially concerning the new element D (or, according to Prof. H. E. Armstrong, Ww!)

Institute of Chemistry

AT the fifty-sixth annual general meeting of the Institute of Chemistry held on March 1, the president, Prof. Jocelyn Thorpe, in moving the adoption of the annual report of Council, said that the register of the Institute contains the names of 6,176 fellows and associates, and more than 750 students. The number of members known to be disengaged is not more than 3 per cent, so that the profession does not appear to be seriously overcrowded. Rather than endeavouring to restrict entrance to the professions generally, he believes in insistence on a high standard of entrance examinations to the universities and colleges in order to eliminate those who are not likely to make really good professional material. The Legal and Parliamentary Committee, under the chairmanship of Sir Christopher Clayton, has rendered useful assistance in matters of public importance in which the profession was concerned. The new Pharmacy and Poisons Act has placed beyond doubt the right of those who practise chemistry, as well as those who practise pharmacy, to use the title 'chemist'. The examinations for National Certificates in Chemistry, conducted jointly by the Institute and the Board of Education and the Scottish Education Department respectively, are having a beneficial effect on the training in science afforded in technical institutions throughout the country. Lately, the Council has discussed the place of chemistry in general education. It seems that in some places chemistry is regarded as too difficult a subject for boys less than sixteen years of age, and that physics and biology should be given the preference as school subjects; the Council proposes to publish the discussion and to invite members to express their views thereon. Prof. Thorpe was re-elected president of the Institute.

Associated Learned Societies of Liverpool and District

AN important stage in the history of amateur scientific circles on Merseyside was a reception at the University of Liverpool on March 3 of the Associated Learned Societies of Liverpool and District, which represents some twenty amateur societies with a membership of about 4,000. The Vice-Chancellor of the University, Dr. H. J. W. Hetherington, who is also president of the Associated Societies, welcomed the gathering, while the Pro-Chancellor of the University, Mr. C. Sydney Jones, said the University is always to be looked upon as a friend and encourager of the amateur scientific bodies of Liverpool. The chairman of the Associated Societies, Mr. W. Mansbridge, in passing a vote of thanks, told how in the past the co-operation of amateur and professional scientific workers that existed in the societies has been to the benefit of each, and the societies have often been of help to the research workers at the University. A tour was then made of the various departments, where exhibits and demonstrations had been arranged. The Associated Learned Societies of Liverpool and District was formed in 1922 to promote co-operative undertakings between the various learned societies, to stimulate the interchange of ideas to the benefit of the societies or of knowledge, and to promote cordial relations between them and the University, the local education authorities and the municipal institutions. The committee has, in the past, arranged a number of joint *soirées* and scientific exhibitions, lectures and excursions to places of scientific interest.

The Autodial for Telephones

TELEPHONE subscribers connected to automatic exchanges who use their instruments frequently will soon be able to obviate in many cases the necessity of making the dialling operations. On the London automatic exchanges, the ordinary number of operations to be carried out is seven. By means of the new autodial, these operations can be reduced to two. The device is contained in a small box on the face of which there is an index of the names of the subscribers most frequently called. When anyone whose name is on this index has to be called, all that has to be done is to set the pointer of the instrument opposite the name required and depress a lever. There is no change-over switch and the instrument does not in the least interfere with the normal use of the telephone. Any number not on the index can be called by the usual method of dialling. The index names correspond with toothed discs, the teeth of which are cut away to form a transmitting code of impulses corresponding to the number selected. The discs clip on to a rotating cylinder so that the combination can be easily changed when necessary. The depression of the lever winds the cylinder sufficiently for one revolution and this is sufficient to generate the train of impulses necessary for completing the call. We understand that subscribers will be able to hire an autodial for a few shillings quarterly It is made either for 25 or 50 names For business houses and intercommunication systems, special forms are made The distribution of the instruments for private installations is made by Dictograph Telephones Ltd , Aurelia Road, Croydon.

Life on the Planets

IT is highly unlikely that there is any life on any planet in the solar system except the earth Dr W. S. Adams, who has himself made some spectroscopic investigations of our fellow planets, has enumerated the factors which preclude the possibility of life on each of them (Science Service, Washington, D C) In the case of Mercury, the planet is too hot and too small to hold an atmosphere Venus has neither oxygen nor water above the dense clouds which hide its surface, but it does have carbon dioxide, which shows that plants, if any, are not numerous The possibility of life is least remote in the case of this planet, but without plant life there can be no animals or human beings. Mars is so small, and its gravity so weak, that its atmosphere is thin It has polar caps suggesting water, but the spectrum shows no free oxygen. The outer planets have temperatures far below zero their great masses enable them to hold dense atmospheres, containing gases which are rare in the earth's atmosphere the poisonous gas ammonia is a fairly abundant constituent of their atmospheres, but oxygen has not been found in any of them Imaginative enthusiasts who project interplanetary journeys in rockets, must envisage a complete departure from the solar system, and conduct an extensive search among the satellites—if any—of some of the nearer stars, if they wish to find a landing place at which they can avoid suffocation at the end of their journey

British Spas and Health Resorts

WE have received the 1934 edition of the official handbook of the British Health Resorts Association, edited by Dr R Fortescue Fox ("British Spas, Inland and Seaside Resorts". London Messrs J. and A Churchill 1*s*. 0*d* net) The book has expanded and contains several new features The section on spa treatment and particulars of British spas has been extended, and health attractions of New Zealand, South Africa and Canada are detailed. Full information is also given respecting seaside resorts, and of the medical values of some of them as winter resorts for convalescents and delicate persons, and a full guide to hotels, hydros, etc , is included The Minister of Health, Sir E Hilton Young, contributes a foreword

Announcements

SIR HENRY GEORGE LYONS, lately director of the Science Museum, South Kensington, has been appointed a Trustee of the National Portrait Gallery, in succession to the late Sir William Hardy

MR. H T TIZARD, rector of the Imperial College of Science and Technology, has been appointed to be one of the Development Commissioners.

THE following appointments in the Colonial Agricultural Service have been made by the Secretary of State for the Colonies Mr. L L. De Verteuil, to be assistant agricultural officer, Antigua ; Mr S M Gilbert, assistant director of Agriculture, Trinidad, to be chief scientific officer, Coffee Research and Experimental Station, Tanganyika ; Mr R O Williams, economic botanist, to be assistant director of agriculture, Trinidad

THE Council of the Royal Society of Edinburgh has made the following awards Keith prize for the period 1931–33, to Dr A Crichton Mitchell, for his paper on "The Diurnal Incidence of Disturbance in the Terrestrial Magnetic Field" published in the *Transactions* within the period of the award ; Neill prize for the period 1931 33, to Dr G W Tyrrell, for his contributions to the geology and petrology of sub-arctic and sub-antarctic lands These prizes will be presented on July 2

IT is reported in the *Moscow Daily News* that a conference is to be held in Leningrad in April at which the study of the stratosphere is to be discussed It is anticipated that some 350 scientific workers will attend this conference, including Profs Joffe, Vavilov, Molchanov and the crew of the stratostat *USSR* It is stated that the Geophysical Observatory has issued a symposium on the first Soviet flight into the stratosphere summarising the scientific material obtained

A USEFUL bibliographical list of geographical books both for university and school use has been issued by Messrs W Heffer and Sons, Cambridge (Catalogue No 422). It contains more than 700 entries classified under various headings for easy reference Now as well as relatively old but standard works are included The list should prove useful to all students of the subject

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A woman lecturer in needlework, hygiene and household science at Bingley Training College—The Education Officer, County Hall, Wakefield, Yorkshire (March 13) Mechanical and automobile engineers in the Ministry of Transport—The Establishment Officer, Ministry of Transport, Whitehall Gardens, S.W 1 (March 15) A district live stock officer and an assistant marketing officer in the Ministry of Agriculture and Fisheries—The Secretary, Ministry of Agriculture and Fisheries, 10, Whitehall Place, London, S W.1 (March 19) An electrical inspector of factories—The Industrial Division, Home Office, London, S W 1 (March 20) A resident lecturer in science, chiefly biology and gardening, at St Hild's College, Durham—The Principal (March 28) Examiners in various subjects of the Matriculation and General School Examination of the University of London—The Secretary to the Matriculation and School Examinations Council, University of London, South Kensington, S W 7 (April 4) Professors of medicine and pathology at the British Post-Graduate Medical School—The Academic Registrar, University of London, South Kensington, S.W 7 (May 4)

Supplement to NATURE

No. 3358 MARCH 10, 1934

Reviews

The Scientific Spirit of the Greeks

The Heroic Age of Science the Conception, Ideals and Methods of Science among the Ancient Greeks By Prof William Arthur Heidel (Published for the Carnegie Institution of Washington) Pp vii+203 (Baltimore, Md The Williams and Wilkins Co ; London Baillière, Tindall and Cox, 1933) 12*s* 6*d*

"WE must endeavour," wrote Plato in the "Timæus", "to construct the four forms of bodies which excel in beauty, and then we shall be able to say that we have sufficiently apprehended their nature " To wrest this sentence from its context, and to take it as a characteristic expression of a prominent aspect of Greek science, is to do no great violence to truth The modern conception of science scarcely becomes recognisable until the days of Galileo, and in any judgment of early science we should remember that our present standards of sufficient apprehension of the nature of a body do not necessarily apply That we believe them to be better is not strictly relevant , the essential factor in judgment must be . given the contemporary standards, what results might have been expected, and what were actually achieved ?

There are certain problems that the world seems inevitably to present to the thinking man For some centuries past, it has been the custom—a custom justified by its success—to attack these problems piecemeal rather than by a grand general onslaught An initial slowness of advance gradually changed to rapid progress, and we now have a body of well-established knowledge unparalleled in the history of the race The ancient Greek was of too fiery an intellectual spirit to wait for the patient accumulation of facts , he took such meagre stock as was available, supplemented it by an acute power of observation, and proceeded with unconquerable enthusiasm to the sufficient apprehension of himself, the earth and the heavenly bodies.

It was a necessary consequence of this uncontrollable burgeoning of the mind that the problems we now segregate into theology, philosophy, science, mathematics and other conventional folds should be fused by the Greek into a single mass , and if the mass appears to us to be of a terrifying heterogeneity, we are not to suppose that it so presented itself to him On the contrary, if Greece has one lesson more than another for modern science, it is that devotion to analysis should not lead to neglect of the synthetic outlook that, in Athens, extracted such brilliant results from such scanty material

In an age when the principal intellectual aim was to solve the universe to-day, or at latest to-morrow, we must not expect to find a humdrum corpus of scientific knowledge increasing by imperceptible degrees, but steadily As Prof Heidel justly remarks, in the epilogue to his valuable and extremely interesting book, the Greek "seems to have felt, as did Wordsworth, that 'the world is too much with us' , its very jostlings gave him a sense of being an alien until he could, as it were, keep it at arm's length long enough to glimpse its meaning Its significance and relations fascinated him—if he could discover these, the brute facts interested him little" It was this imperious passion to unriddle the major enigmas that gave Greek thought both its sublime successes and its gravest shortcomings

Among the latter, a general failure to appreciate the vital importance of experiment is that which the modern man of science will most condemn There is a remarkable unanimity of historians (a body not commonly given to speak with one voice) that the art of experiment, though by no means unborn at that time, was despised rather than encouraged by the educated Greek , and it is certainly true that even Aristotle relates many things as facts that he might easily have disproved by the simplest of experiments It is not that powers of observation were lacking—indeed, few peoples have equalled the Greeks in keenness and accuracy of observation—but that the deliberate arrangement of events for the purpose of defining or extending knowledge appears to have been regarded by them as too slow, too cumbersome or too undignified a method for the intelligent man.

Let the craftsman, the artisan, the slave, deal manually with reluctant matter, while the philosopher employs his time to better advantage with the things of the mind

Prof Heidel has much to say that is new and illuminating upon this verdict He makes the point that, in evidential value, as in principle, there is no reason for giving experiment the preference over observation, and that in some sciences, which are (or may be) quite as exact as the experimental, there is little or no possibility of experimenting "What distinguishes the best scientific procedure of modern times," he says, "is chiefly the refinement of technique, and, in a few outstanding sciences, the recognition of the methodological principles which require an elaborate technique This refinement of technique is due principally to the progressive definition of problems as science has pushed its inquiries farther and farther" While this point of view might be disputed, and while Prof Heidel might be reminded that even astronomy is, in numerous and important respects, an experimental science, we may readily grant him the conclusion he wishes next to draw, namely, that since the Greeks were pioneers, we ought not to expect the same refinement of experiment from them that we demand of modern science

The conclusion is a weighty one, and not the less so for becoming self-evident when thus baldly stated We are made to reflect that, far from being a ready-made tool, the art of experimentation had to be chipped and hewn for long ages before reaching its present Saladin-sword efficiency Our former question recurs What were the contemporary standards, and what relation do the results bear to what might have been achieved ? Prof Heidel shows us that the standards were necessarily low, and that the results were in fact by no means so negligible as is popularly supposed He is able to quote many genuine experiments from Greek authors, and to bring forward evidence that the basic nature of experiment, and its importance, were widely recognised He admits that for the most part such experiments as were made were simple, and served to answer simple questions, and that apparently they were generally undertaken to test theories rather than to discover facts upon which to found theories But he has certainly established the thesis that, within limits, the Greeks knew how to experiment and appreciated the confirmation which a successful experiment provided. Since, moreover, he does not overstate his case, but frankly agrees that there is a great difference between modern science and the achievements of the Greeks, we may the more happily revise our estimate of the 'heroic age of science', and admit a greater debt to Hellas than we had previously acknowledged

In his preface, Prof Heidel says that he hopes to make further contributions to the history of Greek science in various fields That hope will be echoed heartily by all who have the good fortune to read the present volume E J HOLMYARD

The Thyroid Gland

The Thyroid Gland its Chemistry and Physiology By Prof Charles Robert Harington Pp xiii + 222 + 8 plates (London Oxford University Press, 1933) 15*s* net

THERE will be few more interesting chapters in the history of science than that which includes the development of our knowledge of the chemistry and physiology of the thyroid gland Prof Harington's book offers an excellent basis for that chapter He reviews early conceptions of the nature of thyroid function, the gradual definition of ideas through the study of myxœdema, operative and experimental removal of the gland, and replacement therapy, to Magnus Levy's demonstrations in 1895 of the characteristic effect of the thyroid on metabolism

The concurrent story of the study of goitre is outlined from the earliest records to the present day The curious persistence throughout the story, from Pliny, about 2000 years ago to the present time, of certain tendencies, for example to associate goitre with certain drinking waters, is of great interest Geographical, and age and sex, distribution, are discussed in relation both to older theories and to more modern knowledge The inspired attempt of Chatin, early in last century, to correlate the incidence of goitre with low iodine supply, without any idea that iodine is an essential constituent of the gland secretion, has been amply justified by recent work

The chemical study of the thyroid secretion and the exact study of its metabolic action date from much more recent times and follow the discovery of iodine in the thyroid The preliminary studies showed that "the organic iodine compound is attached to a characteristic globulin which, together with a small proportion of an iodine-free nucleo-albumin, constitutes the colloid with which the follicles of the normal thyroid are filled". From there, the account is of work done by Prof. Harington and his collaborators They have shown that the iodine in the thyroid is divided between diiodotyrosine and the characteristic thyroid amino-acid, thyroxine, the former being regarded as precursor of the latter. Thyroxine exerts all the effects on metabolism of thyroglobulin but, on the basis of equivalent iodine content, in less degree. It is further shown that a peptide containing thyroxine as one of the constituent amino-acids, isolated from thyroglobulin by enzymic digestion, is more active than thyroxine alone Prof Harington believes, therefore, that such a compound, possibly one more complex and more active than that isolated, represents the true active principle.

On the physiology side the book is perhaps somewhat less satisfying than on the chemical While it will possibly be agreed that "the immediate cause of goitre is failure of the thyroid gland to obtain an adequate supply of iodine", it is doubtful whether it will also be accepted as settled that "environmental deficiency is the sole cause of most endemic goitre" It seems possible, assessing all the available evidence, that the deficiency, in many cases, may be not primary but conditioned by a multiplicity of factors It would be of great, and not purely academic, interest to find a satisfactory explanation for the persistent popular association of goitre with water or with lime Such beliefs may be as well founded as the ancient use of burnt sponge as a remedy But the water belief cannot yet be shown to bear any relationship to the iodine deficiency theory.

There are other questions, too, that might be asked If the dysthyroidism theory of Graves' disease, as enunciated by Plummer, be rejected on the basis that "no derivative of thyroxine containing less than the full complement of iodine either approximates to thyroxine in activity or exhibits any toxic properties whatever", may it not immediately be reformulated on the basis of Prof. Harington's own statement that "variations may occur in the amino-acids with which thyroxine is combined to form the active secretion, so that the physiological properties of the secretion produced by different glands and under different conditions may not be quantitatively constant" ?

Prof. Harington contends that there is reason to seek the origin of the "thyroid diarrhœa" of Graves' disease outside the gland itself. Anterior pituitary, with its recently discovered thyrotropic hormone, offers itself as an obvious scapegoat at the moment. But then there is the question of whether abnormality of the pituitary is, in fact, associated with Graves' disease The riddle is still to read Those who are interested will find in this book the fundamental chemical and physiological facts with which any theory of Graves' disease must conform

I LEITCH.

Human Reproduction

The Science of Human Reproduction Biological Aspects of Sex By Prof H M Parshley Pp 319 (London George Allen and Unwin, Ltd, 1933) 12*s* 6*d* net

THE author of this book is an American professor of zoology, and from his preface we learn that a large proportion of the population (of the United States ?) refuse to accept religious guidance in sexual matters, and that he aspires to substitute for this guidance the supreme authority of science He has succeeded in giving a readable account couched in comparatively simple language of the structure of the reproductive organs in man, which should be quite intelligible to the average educated person

A very interesting point is the author's explanation of how at the same time the ova are wafted *down* the Fallopian tube and the sperm propelled up it Parker's investigations (published in the *Phil Trans Roy Soc*) seem to show that spermatozoa are quite incapable of such a feat as swimming upwards in the face of a down-flowing current. Apparently they adhere to the walls of the tube, swimming slowly in all directions, and are carried upwards in folds of the wall by an upwardly directed peristalsis The ova, on the contrary, lie free in the lumen and are carried downwards by the current produced by the cilia lining the walls

Like many Americans, the author is a whole-hearted supporter of the Morgan theory of the determination of sex by the 'random' passage of sex-chromosomes into one cell or another. This theory, so facile and at first sight so plausible (especially when represented by simplified diagrams in which all awkward details are left out), threatens to become a dogma in the United States. Yet a wide survey of the animal kingdom shows it to be radically false Sex, one of the most fundamental phenomena of life, must be essentially the same thing wherever it occurs. As a matter of fact, the eggs and spermatozoa of sponges, the lowest

Metazoa, are not very different in their histology from those of man, the highest. There are, however, very many cases where sex is 'determined' entirely independently of any possible intervention by sex-chromosomes In the bee, for example, the male possesses all the kinds of chromosome which are present in the female but they are haploid in the male and diploid in the female In *Rana esculenta*, the edible frog of northern Europe, a large proportion of the tadpoles metamorphose into young females, but of these nearly half change into males during the period of their adolescence, which lasts four years They develop seminal tubes from the peritoneal covering of the ovary, which grow into the ovary and completely destroy it, replacing it by a testes Then there is the classical case of Prof Crew's aged hen the ovary of which was attacked by tuberculosis, and as a result the animal became a cock and produced viable spermatozoa It seems clear that there are fundamentally opposed male and female constitutions, but that the constitution of every individual is a mixture of the two, and that the structural manifestations of sex depend on the proportion of these constitutions and on which gains the upper hand in development

When the author approaches the vital subject of sexual behaviour, he makes some very sensible remarks on birth-control and the necessity of regulating the population But in dealing with eugenics he is less happy He arrives at the conclusion that the object to be aimed at is not the breeding of intellectual men (there might be too many of them and they might become discontented with the positions available for them) but of good men, and that goodness is a heritable quality ! He points out that human sexual behaviour both normal and abnormal presents many analogies with the sexual actions of the higher primates and the same fundamental 'urges' are common to both Here he relies on the work of Dr. S Zuckerman on the sexual life of baboons Zuckerman was until recently prosector of the Zoological Society of London and his work is based on observations on the "Monkey Hill" in the Zoological Gardens and on knowledge gleaned during a six months' tour in Africa Some who, like the reviewer, have had long periods of service on the Council of the Society will not agree with the author and Dr Zuckerman that the ecology of Monkey Hill presents a fair copy of the natural conditions under which these apes live

When we further consider the amendments which the author suggests to the old code of morals prescribed by the "taboos of religion", such as the recognition of sexual promiscuity before marriage, and the permission (to the male) of a certain amount of promiscuity after it, we are enabled in some measure to understand the rise and progress of 'Fundamentalism' in the United States

Agricultural Organisation

The Planning of Agriculture By Viscount Astor and Keith A H Murray Pp xvii + 186 (London Oxford University Press, 1933) 6s net

BRITISH agriculture is unquestionably in a very serious position, and few will disagree with the assertion of the farmers that they are not mainly to blame The essential features of farming that mark it off from other industries are that its programme of production must be definitely settled many months ahead, that the programme, once begun, cannot be modified, and that the amount of production is subject to large and uncontrollable fluctuations from one season to the next In the past few years, these inherent difficulties have been intensified by the rapid fall of prices due to world economic conditions and by the numerous corollaries of that fall It is no longer possible for the landlord to act as a buffer between his tenant farmers and their difficulties, and the State has, of necessity, taken over a portion of this task

State-aid inevitably implies some measure of control by the State The development of the quota system is, presumably, regarded by the authorities as the best way of providing assistance without unduly restricting the initiative and freedom of action of the farmers Viscount Astor and Dr Murray criticise this policy on both agricultural and economic grounds They believe that the future of British farming lies in live-stock, fruit, and vegetables, and feel that the present policy will slow up the change-over to these branches of farming, and is therefore to be avoided They consider that any protection needed by this industry is better given by tariffs, since they are capable of rapid adjustments when necessary; further, tariffs bring in revenue that can, if circumstances necessitate, be distributed to the home farmer as a subsidy or bounty. Finally, quotas, in their opinion, tend to 'canalise' trade to an excessive degree, since some form of bottle-neck organisation is necessary if they are to be worked successfully

Economists are in too many camps nowadays for these views to find universal acceptance The system under which the production of the nations of the world was complementary has, in the opinion of some thinkers, been ended by the discoveries of science and the development of nationalism If the nations are becoming less interdependent economically, the old methods of trading and of financing trade can no longer apply unaltered The evolution of new methods will take some time and there are bound to be initial mistakes Whatever the policy finally adopted, it must take into account one feature of the present depression that distinguishes it from all previous ones its association with abundance—potential, if not actual Those who hold these views consider that the basic problem is how to use abundance to improve the lot of mankind instead of to menace them with recurring unemployment

Geography of Asia

The Continent of Asia By Prof Lionel W Lyde Pp xxii + 777 (London Macmillan and Co, Ltd, 1933) 16*s* net

ASIA covers one third of the land-surface of the globe, and half the world's population is packed into the Indo-Pacific hinterland, the territories between the Indus and the Amur An author attempting to sketch its bewildering varieties of relief, climate and natural resources, and, at the same time, to summarise coherently the effects of geographical control on its products and the activities of its peoples, must be equipped with an immense detailed knowledge and possess literary ability of an exceptional kind

Prof Lyde's earlier work—"The Continent of Europe"—displayed these essential qualifications and they are conspicuous again in the completion of this greater task The book is divided into "General" and "Regional" sections The former, occupying a quarter of the volume, contains the mature reflections of a lifetime on the relations of Asia with the rest of the world, on its orography, its eastern and western lobes and central portion Essays on climate as a whole and in its special aspects are followed by accounts of twelve climatic provinces, the classification being based on genetic control rather than precise statistics These lead naturally to surveys of the vegetation and faunas, of man and his Asiatic differentiations. A final chapter is entitled "Some Controls", and "control" is defined as "the tendency of certain geographical conditions to favour or disfavour certain human responses", while "response" itself may lead to action as well as reaction Amongst other subjects introduced here are the types of social polity which the continent presents on so grand a scale, and its curious deficiency, with few exceptions, in large deposits of those minerals on which European and North American civilisation largely rests

Into such a framework the regional chapters, dealing systematically, but in proper proportion, with each country, are skilfully fitted They have been revised periodically for twelve years before publication and they bear a corresponding finish which reflects the author's mind and its purposes Standardisation of treatment is avoided, the construction of each chapter being determined by the decisive human aspect of the unit concerned Thus though the ways of approaching each country may differ, they converge towards the same object, the correlation of the social, economic and political life of a people with the physical background of their environment and the vagaries of the climate in which they exist Russian Asia, the Lands of the Five Seas, the Anatolian Plateau, Mesopotamia, Syria and Palestine, Arabia, the Iranian Plateau, India, Ceylon, the Indo-Pacific Fan, China and its dependencies, Japan and Manchuria are so studied in turn, and it is unfortunate that a definition of a continent elastic enough to include Ceylon and Japan was not stretched across the South China Sea to embrace those other islands, often grouped together as the East Indies, as well This section is characterised throughout by a critical insight finding expression in incisive conclusions, which, particularly in matters of political geography, do not always coincide with other contemporary views

Short, selected references to literature are given, but those recommended in the case of India and mentioned on p 435 do not appear The book is illustrated with 143 maps and diagrams, and these together with the index, letterpress and binding leave nothing to be desired.

It would be very remarkable if an occasional slip in minor detail was not to be found in such an encyclopædic collection of facts, but they are rare and of little account, though the Shan plateau, crossed as it is by two railways and traversed in all directions by good motor roads and busy mule tracks, should not be described as "very imperfectly known" (p. 500)

The unique character of this important book should assure its systematic use in the geography schools and universities of both Western and Eastern lands. To a reader desiring enlightenment on the grave movements which disturb the whole of Asia to-day, from Kashgar to Colombo in one direction and from Mecca to Mukden in the other, it can be thoroughly recommended Finally, a place must be made for it at once in the front row of authoritative works of reference on Asiatic questions generally

The Coal Problem

(1) *Coal in the New Era.* By Ivor Thomas Pp 224. (London and New York . G P Putnam's Sons, 1934) 5*s.* net

(2) *Smoke and the Atmosphere · Studies from a Factory Town* By Dr J R Ashworth Pp xii + 131 (Manchester Manchester University Press, 1933) 7*s* 6*d.* net

MAN digs up certain black stones from the bosom of the earth and says to them, "Go forth and make heat, power, light, gas and electricity"

Modern civilisation has been largely built up on coal: the fall in the demand for coal is perhaps the most serious industrial problem with which Great Britain is faced. The reasons for the decline are numerous; they include industrial depression, more economic use of coal in industry, smaller domestic purchasing power, competition with foreign coal in export markets and with imported oil in the home markets. The coal question is a tragic example of mishandling; mistakes political, social, economic and technical, have been made of every kind. Even yet there is chaos where there should be order, in spite of repeated attempts by the State and by private bodies to help the industry to better days Raw coal regards gas and electricity as its enemies, and these two great industries are at each other's throats, instead of all three working for the common interests Each section is to-day undertaking costly propaganda on its own whereas they should be working together in the closest harmony. We are repeatedly told that a new era for coal and its products has arrived and that the raw coal sent to the pit-mouth is to be transformed into a variety of more useful and more valuable products, but though the disease has been diagnosed the doctors quarrel as to the remedy.

(1) Mr. Thomas, writing from the point of view of the intelligent man interested in scientific progress, has sought to set out the coal problem and its solutions. "Science to the Rescue" is his chapter heading, explained by such subsidiary titles as "From Pit to Petrol Tank" and "Gas as a Motor Fuel" He is right in his assumption that only science can save the coal industry, though with coal it requires far more than the usual eloquence and sincerity of the missionary to make converts to applying science There is, alas, too much human nature among the ingredients which go to make up the problem Mr Thomas has the courage to set out the political and financial aspects of the question, as well as to advocate the reconstruction of coal as a rationalised industry under a National Power Board His treatment of this question deserves thoughtful consideration, for it represents a growing opinion widely held among the younger generation

Individual capitalistic organisations of moderate size are on their trial, for they have generally failed to overcome post-War difficulties the idea of control of production by the State is growing in favour as countries grow more nationalistic, just as the great advantage of operating an industry as a unit of national size, with unified buying and central selling, is being recognised by many of the nationals

This is obviously a controversial subject but it is one well worth examining, the drift is undoubtedly in the direction indicated

The coal mining industry has many vexed questions to settle—including wages and royalties Its quota system finds few friends among the users, whose grumblings so far have been largely stilled for patriotic considerations, but the complaints of the excessive price charged to the gas industry should be noted This is making gas dearer than it otherwise need be and retarding the development of gas and the consequent elimination of smoke and dirt and fog from our cities. Far too many colliery managers consider that it is their sole duty to bring coal to the surface without any consideration of its quality or ultimate use Perhaps, however, we should remember, as Mr W. G. Gordon has reminded us recently, that a few years ago it was coal that the world wanted and that the utilisation of coal which we are all concerned with to-day is a comparatively new idea.

In consequence of its disorganisation, the returns of the coal industry are very inequitably distributed According to Mr. Thomas, whereas the miner gets 9*s* per ton for his arduous work, the ultimate seller of household coal, after deducting selling and delivery expenses, received 13*s* 9·94*d* in 1932

The more technical portion of the book is marred by a good many inaccuracies and over-statements, but these are minor blemishes in a work which should be widely read. For the future, Mr Thomas pins his faith on the use of coal to produce oil by hydrogenation, on the extension of low temperature carbonisation replacing raw coal, on the development of electricity, and on the use of gas as a motor fuel The amount used in industry, as locomotive fuel and on ships, is expected to diminish

(2) Dr Ashworth deals with another, though in our opinion anything but minor, aspect of the coal problem, the formation of smoke and soot in a manufacturing town—Rochdale—which is particularly unfortunate in this respect He has devised apparatus to measure various features of the evil, in particular the deposited impurities, the horizontal pollution and the suspended matter The hourly and other records taken over a period have enabled a number of interesting deductions to be drawn

Perhaps the most interesting of these has relation to the influence of smoke and hot gases from factory chimneys on rainfall, which is apparently less on Sundays, when the factories are not working, than on the other days of the week A very considerable amount of statistical evidence is cited in support of this conclusion Equally Monday has continuously high rainfall values from 6 a m until 3 p m , when the smoke emission due to starting up the factories is at its greatest In clean areas there is no such unequal distribution of the rainfall on particular days of the week

The influence of atmospheric pollution on light has also been studied, the iodine, methylene blue and photographic methods being carefully studied and compared Sunday being the cleanest day is also that of highest light intensity in Rochdale, whereas in Ventnor and even in London there is little or no difference between the various days of the week in light intensity. Rochdale has only an average light intensity per day of 0 5 compared with 1·6 for London and 6 3 for Ventnor The average deposit per month per square kilometre at Rochdale is 17·2 metric tons, which compares with a figure of 6·4 tons in a residential town like Cheltenham. It is estimated that more than 60 per cent of the total deposit in Rochdale is from factory chimneys.

It is most valuable to have careful records of this kind, and it is to be hoped that they will be collected in many centres Seeing that most of the smoke is preventable, and considering the harm its presence does to health and property, it is a striking indictment of our habit of accepting a state of affairs which no civilised body of men should tolerate

Somehow everything connected with coal has its dingy side in restless, grimy, utilitarian, man-made England E F. A.

Atomic Collisions

The Theory of Atomic Collisions By N. F Mott and Dr H S W Massey (The International Series of Monographs on Physics) Pp xv+283. (Oxford Clarendon Press , London Oxford University Press, 1933) 17*s* 6*d* net

THIS book gives a very complete account of the quantum theory of collisions In an introductory chapter, some theorems of wave mechanics are stated The following four chapters are devoted to such collisions in which the internal state of the colliding particles is not changed, even during the collision, that is, so to speak, collisions of rigid particles First of all, the general formula for the scattering by a central field of force is derived The case of a Coulomb field is discussed in greater detail Then a chapter on electron spin is included, in which great care has been taken to explain the peculiar spin-wave-functions Finally, the collision of two identical free particles and the important rôle of exchange therein is treated

The main part of the book deals with the collisions of electrons with atoms. The first chapter supplies the necessary mathematical tool, namely, the calculation of a solution of a given differential equation which represents an outgoing spherical wave As a special case, Born's approximation is derived The connexion of the exact formula for the scattering by a central field of force with the Born formula as well as with the classical theory is discussed Then a very valuable summary of the methods available for treating collisions with atoms is given, special attention being paid to the more complicated processes such as electron exchange, etc Afterwards, the various kinds of collisions are treated in detail For elastic collisions of fast electrons, Born's approximation can be applied, whereas for medium velocities the distortion of the electron wave by the field of the atom has to be taken into account In both cases the theory compares favourably with experiment, For slow electrons, however, the theory appears to be still far from complete, mainly because there is no approximation for the exchange effect which is sufficiently accurate and at the same time sufficiently easy to handle Even the conditions under which exchange becomes important are not yet exactly known

The theory of inelastic collisions of fast electrons with atoms appears to be almost complete The probability for excitation and ionisation of the atom, the stopping power, the angular distribution of scattered and ejected electrons, can be calculated from Born's method in accordance with experiment More of a qualitative nature are the theoretical predictions about the inelastic scattering of slow electrons by heavy atoms. The scattering of electrons by molecules can be calculated with fair accuracy by adding the scattering amplitudes from the constituent atoms The discussion of the various types of excitation, ionisation and dissociation occurring if a molecule is bombarded by electrons is very clear

Much has still to be done upon the collisions of two heavy particles such as atoms and molecules The book states many important questions, especially in the field of chemical kinetics, and gives the methods for treating them and the results obtained up to the present

The last two chapters deal with Dirac's method of variation of parameters, with the relativistic scattering formula and the calculation of the field of a nucleus from the anomalous scattering of α-particles

There is, we think, no collision problem of any importance which is not mentioned in the book, and for most of them at least a qualitative theory is given But it is of even more value that the book not only compiles the results and theoretical methods, but also points out clearly the conditions under which each method is applicable The standard of the book is rather high, and there are some sections that will appear not easy to read This is, however, only natural, because some of the collision problems, especially those involving slow particles, require rather complicated mathematics The development of the mathematical methods apart from the physical application will be found helpful It is of special value that many results of the authors hitherto unpublished are included in the book, elucidating points that have not been clear even to the expert

The book will, without doubt, be indispensable for everybody doing research on collisions either theoretical or experimental The experimentalist will draw much information from the great number of tables and figures representing the theoretical results Moreover, it will be of great interest to all those who, having a sound general knowledge of wave mechanics, wish to know more about this specially attractive application of it

Electrical Measurements

(1) *High-Frequency Measurements* By August Hund (International Series in Physics) Pp xi+491. (New York McGraw-Hill Book Co, Inc, London McGraw-Hill Publishing Co, Ltd, 1933) 30s net

(2) *Advanced Electrical Measurements* By Dr William R Smythe and Dr Walter C Michels Pp x+240 (London Chapman and Hall, Ltd, 1933) 15s net

(1) THE casual reader may be surprised by the easy confidence with which the publishers imprint "First Edition" on the title page of this book But they are certainly justified, there can be no reasonable doubt that the work will run through many editions, for it is excellently done, and is very easily the best that has yet appeared on this complex subject It would be difficult to find any type of problem in high-frequency measurement which escapes mention This catholicity, indeed, brings with it one disadvantage which might well be corrected in a later edition the range of methods covered is so wide that critical comparison, on which the reader might base a choice of method, is insufficiently provided It would be genuinely helpful if the author would follow "Baedeker" and the "A A Handbook" in attaching stars to recommended methods

In the eighteen chapters of the book, the author deals, with a great deal of wisdom and helpful inter-relating comment, with the special technique of measurements at high frequency, giving special attention to the wide range of physical phenomena which must be kept in mind if the ultimate indication is to be truly interpreted in terms of the quantity to be measured The first chapter deals with fundamental relations and circuit properties, and the second with high-frequency sources and other useful laboratory apparatus. In the third the author quite illogically, but quite rightly, includes the measurement of minute direct currents in his discussion of measuring systems for high-frequency currents, later chapters deal with the measurement of voltage, frequency, capacitance, self-inductance, mutual inductance and coupling, effective resistance, high-frequency power and losses, decrement, power-factor, phase difference and sharpness of resonance, and ferromagnetic properties. A very satisfactory chapter on tube measurements deals with a wide range of thermionic tubes and associated circuits, and this is followed naturally by a chapter on modulation measurements.

Amongst the most valuable and novel sections of the work are the treatment of determinations on aerials and lines, and on wave propagation. On both these aspects of high-frequency measurement it has been extremely difficult for the student to find safe guides without a wide search of the literature. Should he require more information than can be compressed into these chapters, he will find the author's selection of references at once generous and judicious. The two remaining chapters deal with piezo-electric apparatus and with miscellaneous measurements and data.

The first edition of a work, by one man, on this heroic scale, cannot be free from minor blemishes. The language frequently has a flavour of incomplete translation from the German: the 'thermocross', the 'stoic metal', the 'step-over resonator', the 'space condenser' and the 'spacious pole' are unfamiliar and a little disturbing. There are occasional lapses from the generally high level of clarity, precision and care; the statement that "this alloy has a high temperature coefficient" comes to an untimely end before we have learned what property it is that varies so rapidly with temperature. Similarly "a sensitive galvanometer (10^{-10})" is mysterious. But these flaws, such misprints as those in the formulæ of pp. 22, 43, and 211, and the inadequate explanation of "bisymbolic multiplication" by mere reference to a paper of 1920 are amply offset by corresponding high peaks in the book. As typical peaks we may cite the matter of pp. 98, 103, 124, 131 and 230, and we may rejoice that on p. 185 the author has given the circuit values that are required to preserve the circuit diagram of a beat-frequency generator from being a snare and a delusion. The next edition will doubtless recognise the cathode ray oscillograph as a photographic recorder and not as a merely visual device. Meanwhile the first edition is a great work.

(2) Drs. Smythe and Michels have produced a useful handbook for the instructional laboratory, but the title which they have chosen is somewhat too wide for the scope of the work itself. The conventional methods for the measurement of resistance, current, potential difference, quantity of electricity, and magnetic properties are adequately discussed, without any revolutionary improvement in exposition over previously available works.

Measurements on vacuum tubes (that is, diodes to tetrodes) and on high-frequency circuits are treated in a summary and rudimentary way, while the chapters on alternating current work are likely to leave the student a good deal to unlearn on the relative merits of different devices. The remaining chapters, on electricity in gases, electrical thermometry, radiation measurements and electrochemical measurements are more useful than the others, because they are less readily found elsewhere.

Review of Physical Chemistry

(1) *Introduction to Physical Chemistry*. By Prof. Alexander Findlay. Pp. vii + 492. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1933.) 7*s*. 6*d*.

(2) *Recent Advances in Physical Chemistry*. By Dr. Samuel Glasstone. Second edition. Pp. viii + 498. (London: J. and A. Churchill, 1933.) 15*s*.

(1) PROF. FINDLAY'S book includes all that a student beginning the systematic study of physical chemistry requires, and is of such a standard that it can serve as an introduction to the more advanced parts of the subject, the references to the literature which are given also being very useful in the latter respect. The historical method is generally followed, yet in all parts the treatment is thoroughly modern, the recent developments of the subject being adequately dealt with. The mathematics required goes no further than the elements of the calculus, without which no progress can be made in the study of physical chemistry.

The book commences with a chapter o constitution of matter, including atomic numbers, isotopes, radioactivity and the electronic theory of valency. The following chapters deal with the properties of gases, liquids and crystalline solids, including crystal structure. The explanation of the Joule-Thomson effect on p. 56 requires modification, since a gas may obey Boyle's law and yet exhibit a Joule-Thomson effect. The study of dilute solutions follows, all the fundamental equations being deduced; and here, as in the rest of the book, an excellent feature is the adequate discussion of experimental methods and apparatus. This section includes electrolysis. Thermochemistry, homogeneous equilibrium, reaction velocity, catalysis and thermodynamics, including an elementary account of Nernst's theorem, follow The book then deals with strong electrolytes, activity, hydrogen ion exponent, hydrolysis, indicators, titrations and buffer solutions, and this part of the book is deserving of special commendation for the clearness of the treatment and the adequacy of the information conveyed in a reasonable space. In the thermochemical sections it would perhaps have been better if the author had used the modern abbreviations 'g cal' and 'k.cal' instead of 'cal.' and 'Cal', which sometimes lead to error.

The chapter on electromotive force is carefully written and comprehensive, although an example of the introduction of the equation for liquid junction potential in the case of an actual cell would have been useful, since this matter is one which often proves difficult to students, particularly in the signs The rest of the book contains chapters on photochemistry, heterogeneous equilibrium, the phase rule (which is illustrated by a very well-chosen set of examples), adsorption and the colloidal state A good collection of numerical and other exercises is given at the end of the book

Prof Findlay's book is an excellent introduction to its subject. Without suffering from the defect of many elementary works, that of being too sketchy and avoiding difficult matters, it is yet well within the comprehension of the student Anyone who masters the course provided will be well on the way to a sound knowledge of modern physical chemistry, and since this subject now has such important bearings on other sciences, the book should make an appeal to a wide field of users It is excellently produced and the price is very moderate

(2) Dr Glasstone's book, which has reached a second edition after two years, appeals to the more advanced student, who has already mastered the contents of such a book as the preceding After the fundamentals have been dealt with, the teacher or student is faced with a large field of more recent and more advanced work which it is impossible to cover in the part of the year generally devoted to advanced physical chemistry in university courses. Some selection is necessary and Dr Glasstone has made a popular choice of subjects

The first chapter deals with the structure of the atom and the modern theory of valency. In the new edition a section on wave mechanics appears, and although the treatment is extremely sketchy and on the lines of the "Annual Reports" of the Chemical Society, it may serve to give an idea of the possible meanings of expressions now used rather vaguely by some chemical authors Recent work on nuclear disintegration, the neutron and the positive electron is mentioned The chapter on the parachor illustrates the applications in the determination of structure The chapter on dipole moments has been extended to include an elementary treatment of rotation, that on molecular spectra now contains a discussion of potential energy curves, and as in the first edition also deals with the Raman effect Homogeneous gas reactions are dealt with in more detail, including a discussion of activation energy and reactions in solution The chapter on photochemistry has been improved by a fuller discussion of reaction mechanism Surface potentials are now dealt with in the chapter on the properties of surfaces The chapter on heterogeneous catalysis covers the field very well in a limited space. Strong electrolytes are dealt with too summarily to be quite satisfactory, and the chapter devoted to them could with advantage have been twice the present length, some rather speculative material from other sections being sacrificed The last chapter, on acid-base catalysis, gives an adequate review of the subject

Within the limits of about 500 pages, the author has managed to give a survey of a few selected parts of modern physical chemistry, which is perhaps as satisfactory as is possible No one will consider that every section is adequate and most teachers will wish that other subjects in which they are interested could have been included This would, however, have defeated the object of the author in giving a concise yet adequate survey of a few topics, and would have caused the book to grow to at least double its present size The references to the literature will enable the teacher to equip himself for lectures and the keen student to extend the knowledge of subjects in which he has been interested by the author

Dr. Glasstone's book fills a well-defined place in the literature and there is little doubt that it will remain popular for some time, especially if the author takes such pains to keep the material up to date as he has in the present revised edition The book is well printed on a rather heavy paper and is somewhat expensive for its size

J. R PARTINGTON.

Short Reviews

Anthropology

Valenge Women the Social and Economic Life of the Valenge Women of Portuguese East Africa An Ethnographic Study by E Dora Earthy (Published for the International Institute of African Languages and Cultures) Pp xi+251 + 24 plates (London Oxford University Press, 1933) 25*s* net

ALTHOUGH the entry of women into the anthropological field has begun to fill what was for long a serious gap in ethnographical investigation, much has still to be done The value of observation from the woman's special point of view is well illustrated by Miss Earthy's study of Valenga women The Valenga were described to a certain extent by M Junod in his book on the Bathonga, but Miss Earthy has carried his observations further; and writing with the place and function of women in the community more particularly as the subject of investigation, she has given a fresh orientation to subjects usually regarded too exclusively from the point of view of the male members of the tribe This is especially to be noted in the account of such a topic as marriage, and appears very clearly in her account of the details of the observances which precede, accompany and follow the rite It also has an important influence on the account of family relations

The most valuable contribution to our knowledge, however, will be found in the account of female initiation, where the author has been able to add to her generalised account of the rite, the recollections, reported in detail, of individual initiates who had undergone the ceremony at varying periods in the past It has thus been possible to note changes which have taken place in the rite, and to draw inferences as to its original character from observances which have vanished in recent years

La race, les races. mise au point d'ethnologie somatique Par Prof George Montandon (Bibliothèque scientifique) Pp 299+24 plates (Paris · Payot et Cie, 1933) 25 francs

PROF G. MONTANDON, now professor of ethnology at the École d'Anthropologie, Paris, has given us in this book an introduction to the study of the races of man which is intended for both the beginner and the layman He opens with the study of 'race', defining it, and then dealing with the various methods of study and the characters by which race is differentiated in man Particular attention is paid to the latest developments of the study of heredity as applied to human races, and the evidence which may be afforded by the blood groups is demonstrated. He then deals with racial origins and distribution, electing the hologenetic in preference to the monogenetic point of view. Next he passes on to the description of the significant physical characters in each of the principal races of mankind, classifying them under the main headings of pygmies, negroids, Ved-Australoids, Mongoloids and Europoids M. Montandon's concept of racial filiation leads to an original plotting of racial migrations, which would bring the earliest immigrants into America by way of the south instead of the more generally accepted north Here he accords with the theories of M Rivet and others M Montandon expounds difficult material with great clarity

Biology

La paléontologie et les grands problèmes de la biologie générale 1 *L'Évolution, adaptations et mutations, berceaux et migrations* Par Prof Charles Fraipont et Dr Suzanne Leclerq (Actualités scientifiques et industrielles, 47) Pp 38 9 francs 2 *Adaptations et mutations, position du problème* Par Prof C Fraipont (Actualités scientifiques et industrielles, 48) Pp 26 6 francs (Paris Hermann et Cie, 1932)

THESE two pamphlets discuss certain evolutionary problems from the palæontological point of view Part 1 considers the question of 'cradles' or points of origin of species, and their subsequent migrations Maps are given showing the geological as compared with the present distribution of various plant and animal groups The plants considered include certain Marattiales, the tropical genus *Engelhardtia* of the Juglandaceæ, *Juglans*, the Ginkgoales, Araucarians, *Taxodium*, *Sequoia* and *Eucalyptus* The animals include the Athyridæ (Brachiopods), the Rhynchocephalians, the mastodons, elephants and horses It is, of course, well known that these groups show marked contraction in the areas occupied by them during successive geological periods This the authors call "centripetal concentration", and they draw the much more debatable conclusion that each species or group began with a maximum distribution—often world-wide—which has since undergone progressive reduction

The theory of centres of origin is thus denied, the alternative being that a species is derived simultaneously over the whole of its area from a previous species—a view which many will find unacceptable

Part 2 is a short review of theories of transformism, in which the Lamarckian principle is upheld, but without any new evidence in its favour. The conclusion is expressed that adaptation is the basis of the formation not only of species but also of genera, orders and all important systematic groupings. Many modern biologists would consider this extreme view to be gainsaid by a mass of evidence, particularly from systematic botany

R. R G.

Life and Living a Story for Children By Dr E P Phillips Pp xiv+152 (Ashford L Reeve and Co, Ltd, 1933) 5*s* net

Dr Phillips has aimed at presenting the facts underlying problems of life which are usually taboo in the curriculum of the adolescent boy or girl The delicate, yet straightforward, manner in which he tells the story of sex, evolution and heredity is striking In fact, we may say that it is the best exposition of the subject of this standard we have read

The subject matter is one complete whole The story opens with reflections on life in general Then follow several chapters devoted to various forms of reproduction in the plant and animal kingdoms, leading up to man The structure, evolution, and psychology of man is then dealt with in more detail Civilisation and culture receive treatment in the last several chapters, where marriage, morals and religion are discussed

It is a pity that Dr Phillips has not given less space to sex and devoted more to certain other aspects of the biology of life Much of the material on religion and morals, too, we think, should have been curtailed in a book meant for readers of such tender years

Unfortunately, people are seldom prepared to buy such books for their children, few schools will be able to afford the price But, though the aim of the author is rather narrow, and not a general survey of biology, it is an excellent book, and, in schools, would form a splendid supplement to a more formal treatise As a home reader it is most desirable The author has a compelling style, and many of the diagrams are well executed and refreshingly original in style

Invertebrate Zoology By Prof Robert W Hegner Pp xiii+570+8 plates (New York The Macmillan Co, 1933) 20*s* net

This work has grown out of the revision of the author's "Introduction to Zoology" (1912) and is intended for students who have already taken their first course of zoology and desire to obtain a more comprehensive knowledge of the invertebrates While prepared primarily for American students, and citing wherever possible American examples, it will be found useful by students elsewhere, as it is written in an interesting manner and deals adequately with the principal features of structure and biology of representative members of the respective groups

The first 118 pages are devoted to the Protozoa and, as would be expected from the author's expert knowledge of this phylum, contain a trustworthy and clear account in which the parasitic forms receive their due, but not an undue, share of attention Praiseworthy features of the book are its attention to the biology of the groups and the inclusion at the end of each of the more important groups of a brief history of our knowledge of the group A short bibliography is appended to each chapter A few of the smaller groups are rather summarily dealt with; for example, the Brachiopoda, Chætognatha and *Phoronis* are all contained in four pages The statement that the larva of *Phoronis* resembles a trochosphere may lead to misapprehension, and the body cavity of Nematoda should not be called a cœlom The author has been, as he states, at considerable pains to bring his book up to date and he deserves commendation for his success in dealing with a great body of material so skilfully

Birds of the Falkland Islands a Record of Observation with the Camera By Arthur F Cobb Pp 88 (London H F and G Witherby, 1933) 7*s* 6*d* net

The contents of the volume are practically all, if not entirely all, the written result of the author's own seven years' residence on Bleaker Island and other islands of the group It is not, perhaps, intended to be a scientific treatise on the birds of the Falklands, nor to be an exhaustive list of the birds which occur there, on the other hand, nobody who reads the book can fail to find much in it that is both novel and interesting No descriptions are given of the various birds referred to The letter-press deals entirely with notes on the range, habits and nidification of each species Altogether it gives notes on thirty-one species of birds found on the islands, including geese and ducks, penguins, albatrosses and gulls, waders and birds of prey

The photographs which accompany the letter-press are very good and are of especial interest, for the author has taken pains to include many which show the type of country the birds inhabit, while there are many excellent plates of breeding haunts, nests and eggs

This is a little book which can be recommended with confidence to anyone with an hour to spare who would like to learn something hitherto unrecorded about the birds of the far-off Falkland Islands It is well got up, the printing good and the misprints rare

Chemistry

Qualitative Chemical Analysis certain Principles and Methods used in Identifying Inorganic Substances together with a Systematic Survey of the Chemistry of these Materials By Dr Roy K McAlpine and Dr Byron A Soule (Based upon the text by A B Prescott and O C. Johnson) Pp. xii+696 (London Chapman and Hall, Ltd, 1933.) 21*s* net

This manual is much more than a treatise on qualitative analysis, since it contains a mass of general information on the elements and compounds which are likely to be met with in the analysis of inorganic materials, including the less common elements It is provided with full references to the literature The group separations are the usual ones, but the tables for each group are arranged in an unusual symbolic form which is far from clear. On account of the large amount of detail, the work is not suitable for the elementary student, who requires a clear set of tables, but the advanced student, the teacher and the practising analyst will find it of interest and value. With so much detail, some mistakes are almost inevitable, as when dithionic acid is said to be obtained (p. 511) by the action of carbon dioxide on barium dithionate, and the product of the action of stannite on bismuth salts is given as bismuth oxide (BiO) on p. 244 and (correctly) as bismuth on p. 224. The long section on balancing equations (pp. 629–656) is of doubtful value, and that on solubility product (pp. 44–137) is, as the authors recognise at the end, too far removed from practice to serve as a safe guide in the laboratory. The book is one which every chemical laboratory could usefully have available for reference.

A Short Organic Chemistry. By Dr. F. Sherwood Taylor. Pp. viii + 378. (London: William Heinemann, Ltd., 1933.) 5*s*.

THE present book is an abridged form of the larger work by the same author and contains those parts of the subject required by the first year student. The theoretical parts are almost as full as in the longer book and the treatment of the simplest and most important compounds remains almost unaltered. Experiments are described, so that the book gives a complete course in elementary organic chemistry. There are also questions and numerical and other problems, with answers. The text is clear and accurate and the brief descriptions of large-scale operations are much more up-to-date than is usual in such books. The modern formulæ of the carbohydrates are given. The discussions of theoretical matters, such as stereoisomerism and the structure of benzene deserve special commendation. Dr. Taylor's book is a very satisfactory course of elementary organic chemistry and can be recommended both for schools and for junior students in universities.

Laboratory Tables for Qualitative Analysis. Drawn up by the Demonstrators in Chemistry, University of Manchester. Fourth edition, revised and rewritten by Dr. Colin Campbell and J. B. M. Herbert. 17 cards. (Manchester: Manchester University Press, 1933.) 3*s*. 6*d*. net.

THESE tables have been familiar to several generations of students passing through the Chemistry Department at Manchester and their excellence has been amply demonstrated over a long period of time. In their new form an alternative scheme for the separation of phosphoric acid in Groups III–IV is given, and two sheets on the less common metals, Be, Mo, Ti, V and W, provided. The explanatory notes, a very valuable feature of the tables, remain, but have been revised when necessary in the light of modern theory. These tables provide a scheme of qualitative analysis which has been thoroughly tested and their use can be recommended in all chemical laboratories.

Chemical Calculations: their Theory and Practice. By A. King and Dr. J. S. Anderson. Pp. x + 181. (London: Thomas Murby and Co.; New York: D. Van Nostrand Co., Inc., 1933.) 4*s*. 6*d*. net.

THE present collection of examples is accompanied by explanatory matter which is found in all the usual textbooks and could quite well have been omitted. Whilst brief summaries of the theory are desirable in the case of books of calculations on physical chemistry, they take up space and add to expense in elementary works. The examples given are very suitable for students taking the Intermediate Science and Higher School Certificate examinations. Answers are provided to alternate problems only. The calculations in volumetric analysis are all based on the use of normalities, and an insistence on this will remove the habit acquired by some students of working out such results by unnecessarily long and unscientific methods. The book is a good and straightforward collection of problems which should fulfil the purpose for which it was written.

(2) *Tables for the Development of the Disturbing Function: with Schedules for Harmonic Analysis.* By Ernest W. Brown and Dirk Brouwer. Pp. v + 73–157. (Cambridge: At the University Press, 1933.) 10*s*. 6*d*. net.

(3) *Vierstellige Tafeln der Kreis- und Hyperbelfunktionen, sowie ihrer Umkehrfunktionen im Komplexen.* Berechnet und erlautert von Robert Hawelka. Im Auftrag des Elektrotechnischen Vereins E.V. in Berlin, herausgegeben von Prof. Dr. Fritz Emde. Pp. v + 109. (Braunschweig: Friedr. Vieweg und Sohn A.-G., 1931.) 10 gold marks.

(1) THIS, the fifth part published, contains a frontispiece photographic reproduction of a letter from Henry Briggs to John Pell. Dr. Thompson hopes to produce another part containing the logarithms of numbers from 10,000 to 20,000 some time this year.

(2) These tables give coefficients designed to facilitate the numerical development of the disturbing function in planetary perturbations. Writing

$$(1-\alpha^2)^s(1+\alpha^2-2\alpha\cos S)^{-s}=\tfrac{1}{2}G_s^{(0)}+\sum_{i=1}^{\infty}G_s^{(i)}\alpha^i\cos iS,$$

Tables I–IV give eight place logarithms of the G's for $s=\frac{1}{2}, \frac{3}{2}, \frac{5}{2}, \frac{7}{2}$, $i=0,1,2, \ldots, 11$, with the argument $p=\alpha^2 - (1-\alpha^2)$ in the interval 0·00 – 2·50. Table V gives coefficients of the expansion of $G_i^{(i)}$ in powers of $(p-3)$ and $(p-4)$ Tables VI and VII give $(1-\alpha^2)^{\frac{1}{2}} G^{(i)}_s$ for $i=0-4$, $s=\frac{1}{2}, \frac{3}{2}$, with the argument α in the interval 0.900–0.950 The remaining tables give certain special data. Schedules for harmonic analysis are appended with fully worked examples

(3) These useful tables give, to four decimal places, circular and hyperbolic sines, cosines, tangents and cotangents of the complex argument $\frac{1}{2}\pi x+iy$, and the corresponding inverse functions The unit of the real part of the angle being a right angle, the whole complex plane is covered by taking x from 0 to 1, y from 0 to 1 and then y^{-1} from 1 to 0, all at interval 0.02 A similar device is adopted for the inverse functions Printed first differences are given both down and across the tables Where linear interpolation is insufficient, exponential interpolation is used by means of an auxiliary table The auxiliary tables, nomograms, and reliefs of the functions are in a separate removable part, which makes their use very convenient L M M -T

Theory of Functions: as Applied to Engineering Problems Edited by R Rothe, F Ollendorff and K Pohlhausen Authorized translation by Alfred Herzenberg Pp x+180 (Cambridge, Mass: Technology Press, Mass Institute of Technology, 1933) 3.50 dollars

The well-known German book, "Funktionentheorie und ihre Anwendung in der Technik", published in 1931, is now available in an English translation The first section, written by R Rothe of Berlin, is devoted to a mathematical discussion of the functions required in the solution of many advanced engineering problems It deals with the complex variable, line integrals and their relationship to potential theory, complex integration, power series and Laurent's series, residue theorems and singularities

The second section is concerned with the applications, and each problem is dealt with by an expert Electric and magnetic fields are discussed by W Schottky, two-dimensional fields of flow by K Pohlhausen, field distribution in the neighbourhood of edges by E Weber, the complex treatment of electric and thermal transient phenomena by F Ollendorff, and the spreading of electric waves along the earth by F Noether

The text is well written though essentially brief, and it is claimed that the book is the first authoritative work on its subject in English It should certainly be of great value to all who are interested in the study of those new practical problems to which the advance of science continually gives rise.

Cours de mécanique rationnelle Par Jean Chazy (Cours de la Faculté des Sciences de Paris) Tome 1 *Dynamique du point matériel.* Pp v+392 (Paris Gauthier-Villars et Cie, 1933.) 70 francs.

The book before us is the first volume of a course in mechanics given by the author at the Faculty of Science at Paris. In accord with its sub-title, it deals with vectors, the fundamental principles of dynamics, general theorems, the motion of a particle—rectilinear, curvilinear and upon a surface—and finally, with motion relative to the earth.

In characteristic French style, there are no exercises for the reader, whilst the text is mainly devoted to a discussion of general theorems, very few particular cases being deduced The simple pendulum, for example, is first worked out as an elliptic integral, whilst the simple case of replacing $\sin\theta$ by θ is disposed of in a short note at the end The whole course is nevertheless very useful and interesting, but the price is somewhat high for the average British student

Miscellany

(1) *Goethe als Chemiker und Techniker* Von Paul Walden Pp. 87 (Berlin: Verlag Chemie G m b H, 1932) 2 gold marks

(2) *Gothes naturwissenschaftliches Denken und Wirken drei Aufsatze herausgegeben von der Schriftleitung der Zeitschrift "Die Naturwissenschaften"* Pp iii+99 (Berlin Julius Springer, 1932) 3.60 gold marks.

Goethe's interest in natural science is an outstanding characteristic of his all-embracing genius His writings often display a detailed knowledge of the processes of Nature, and his intuitions in many instances are almost prophetic. When he was twenty years of age, he made experiments with the "Liquor Silicium" (1769) which led him to the view that a great deal can be discovered about the nature of the elements by paying attention to the geometrical arrangement of their particles In 1795 he wrote to Humboldt, "you enquire into the mysteries of nature through its elements, whereas I do by watching their configuration" Indeed, this is the fundamental principle of the colloidal theory which developed later with such remarkable results Already in 1786, Goethe had noticed that the crystals of common salt take various forms—an indication, he wrote, that they are not pure So great was his faith in natural configuration that he proclaimed, in the same year, that mineralogy without chemistry cannot progress one inch. His interest in the science of matter remained with him throughout his life In 1819, he was much puzzled by the constitution of coffee, and when he made the acquaintance of young Runge, who was later to discover aniline, Goethe gave him some coffee beans suggesting that their analysis might interest him One year later, in 1820, Runge communicated to Goethe his discovery of cafein

A score of interesting details about Goethe's scientific views and the state of science during his lifetime, will be found in the two pamphlets under review Thus we are told how Goethe came to study chemistry and its technique, and what are his most original views on the subject. A supplement of thirty pages in the second pamphlet gives a short analysis of his main achievements in the various branches of physical science. T. G.

(1) ***Basic German for Science Students With Vocabulary and English translations of the German Passages*** By Dr M L Barker Pp xi+164 (Cambridge W. Heffer and Sons, Ltd , London Simpkin Marshall, Ltd , 1933) 6s net

(2) ***The Basis and Essentials of German containing all that must be known of Grammar and Vocabulary in order to express the most frequently recurring Ideas*** By Charles Duff and Richard Freund. Pp xix+113 (London Desmond Harmsworth, Ltd , 1933) 3s 6d net

(3) ***A German Reader for Biology Students Passages from Recent German Scientific Publications*** Selected and arranged by Prof H G Fiedler and Dr G R de Beer With a Vocabulary by Herma E Fiedler Pp vi+92 (London Oxford University Press, 1933) 5s

(1) In twenty-four pages, Dr Barker crowds in the essentials of German grammar in tabloid form and as footnotes to selected passages from the Bible The rest of the book gives general passages from scientific works in German with English translations, and more technical selections referring to chemistry, zoology, botany, physics, mathematics and medicine Unfortunately, only one English rendering is generally given to a German word, although it often has other equally important significations

(2) Equally useful for the general reader is the book by Messrs Duff and Freund Though they give the minimum of grammar, however, they stress the importance of the vocabulary, which is selected and presented in such a way as to cause the least difficulty to an English reader The authors have compiled a large number of German books, noting down the words which occur more often and drawing statistical lists of them They selected for their book those with the highest coefficient, and divided them between those which are similar to their English equivalent, and those which are different Some sound guiding principles here and there help the reader to understand the use and memorise whole lists of words

(3) The work compiled by Prof. Fiedler and Dr. de Beer is simply a selected series of passages from recent German scientific literature, supplemented by an appropriate vocabulary. This reader is intended to be used by students of biology as a supplement to a "First German Course" by Prof Fiedler and F. F Sandbach

The Laboratory Workshop a Simple Course in Apparatus Making and the Use of Tools. By E H Duckworth and R Harries Pp xi+246 (London · G. Bell and Sons, Ltd., 1933) 10s net

This book contains information necessary to the man who has what Dewar called "the use of his hands", but who has not had workshop training, and is thus penalised in much loss of time and endeavour when setting himself to make and mend models, instruments and apparatus. Here also can one learn what materials are most serviceable, and how they are described, and where obtained ; what are the most useful tools , and many suggestions, by the way, about the value of second-hand oddments and out-of-the-way uses for common things ; also valuable sections on glass-working and electrical wiring, with much more of the lore of an experienced laboratory assistant All this is made plain by a large number of clear drawings, over which much labour must have been spent On the other hand, of the two photographs comparing an attic workshop with one for a laboratory, uncertainty may be felt whether to admire the attic or be uneasy about the laboratory , partly no doubt because the detail available is insufficiently informing Many examples have been included of actual constructions of demonstration apparatus and models

One lack that will almost certainly be felt, however, is the determined omission of even simple lathe work it is not easy to understand how anybody in a position fully to utilise the help of this book will be satisfied without the service of at least a simple form of lathe No doubt a later edition will include this extension, since a knowledge of the proper use of the ordinary cutters is not easy to obtain W J G

A Retired Habitation a History of the Retreat, York (Mental Hospital) By H C Hunt With a Foreword by Dr B Pierce and a Chapter by Dr N Macleod Pp xvi+144+12 plates (London H K Lewis and Co , Ltd , 1932) 7s 6d net

The man in the street and the educated layman are extraordinarily uninformed on the subject of the care and treatment of the mentally afflicted, so that it is very interesting to read the history of "The Retreat, York", a title which is very familiar to many The title "A Retired Habitation" is, we think, a great mistake, for it does not convey any indication of the contents of the book, especially when those contents consist of the history of a very great and humane undertaking.

Mr Capper Hunt, the steward at "The Retreat", has given us a very simple and readable account of the development of this registered hospital for the treatment of mental disorder, but we could have wished that he had made it much fuller and given greater detail

Nevertheless, it is a fascinating story and very well presented The extraordinary kindness and consideration shown to the mental patients in the far off days of the early nineteenth century by the nursing staff appointed by the Friends are an object lesson to many of the twentieth century The same spirit has always prevailed, and to-day the standard of nursing at "The Retreat" is second to none, and to the late Dr. Bedford Pierce the modern mental nurse may well be very grateful for all he did to secure the "one portal" entry by examination to the State Nursing Service The book is very well presented and the illustrations excellent.

Nowe Drogi Nauki: Kwanty i Materja. Napisał Dr Leopold Infeld. (Z Dziedziny Nauki i Techniki, Tom 2.) Pp. x+284+6 plates. (Warszawa: *Mathesis Polskiej,* 1933.)

DR. INFELD's "New Developments in Science" presents to Polish readers an account of the most recent advances in physics and chemistry, particularly in the domain of sub-atomic phenomena and the structure of matter. The author opens with a reference to Pascal's views (1647) on the aims of physical inquiry and, after a brief historical sketch, proceeds to describe current ideas concerning matter and energy, X-rays, the quantum theory and the new wave mechanics. Attention is directed to the important discoveries of the last few years, including the Compton and Raman effects.

The book, which is well-printed and well-bound in cloth, is illustrated with some good photographs and should serve to acquaint Polish students with the latest developments and discoveries in the borderland of physics and chemistry.

Physics

Introduction to Theoretical Physics. By Prof. John C. Slater and Prof. Nathaniel H. Frank. (International Series in Physics.) Pp. xx+576. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1933.) 30s. net.

THIS is, in some ways, a remarkable book. The authors are convinced that the teaching of physics by way of a series of separated and more or less watertight courses prevents a student from understanding the unity of physics. Moreover, many problems concerning the structure of matter are necessarily discussed in terms of wave mechanics, and a knowledge of wave mechanics again demands a thorough grounding in classical physics. The authors, therefore, with amazing courage, have endeavoured to build up, in the compass of less than six hundred pages, a consistent and comprehensive picture of modern theoretical physics which shall be something more than a collection of disjointed chapters on unrelated topics.

This task requires some forty-two chapters and the authors are not afraid to begin with such elementary notions as are needed for a brief (and possibly to the pure mathematician inadequate) discussion of power series and Taylor's theorem, exponential methods for the solution of differential equations illustrated by simple physical applications, damped and forced oscillations, vector forces and potentials. Fifty-eight pages of this work bring us to Lagrange's and Hamilton's equations, phase space, precessional motion, vibrating strings and membranes, elasticity, fluid and heat flow. Thence we are led to potential theory, Maxwell's equations, electromagnetic waves, and electron theory. Huygen's principle and Fresnel and Fraunhofer diffraction phenomena are disposed of in twenty-six pages, and the way is now clear for discussions of wave mechanics, Schrodinger's equation, the correspondence principle, matrices and perturbation theory. Then within the limits of about a hundred and fifty pages the authors find space to discuss compactly but very clearly some of the details of atomic and molecular structure, equations of state, nuclear vibrations, collisions, electronic interactions and electronic energy of atoms and molecules, Fermi statistics, and dispersion, dielectrics and magnetism. The book is a remarkable example of unhurried and unostentatious compression, and the authors are to be congratulated on the result of their endeavour "not to teach a great collection of facts, but to teach mastery of the tools by which the facts have been discovered and by which future discoveries will be made".

The book is admirably produced. Each chapter is followed by a set of problems, and judiciously selected references will aid the student in his future reading. A. F.

The Electromagnetic Field. By H. F. Biggs. Pp. viii+158. (Oxford: Clarendon Press; London: Oxford University Press, 1934.) 10s. 6d. net.

AT its lowest, the mathematical instrument of vector algebra is a labour-saving device, and in dealing with electromagnetic theory time spent in learning how to use the instrument is amply repaid. In many general textbooks on electricity and magnetism the introduction of a mathematical technique which may be unfamiliar to probable readers is avoided; and students of physics often find considerable difficulty in bridging the gap between the Cartesian treatment and the vector treatment usually adopted in more advanced treatises. It is to such students that this book of Biggs is addressed.

The use of vector notation in the representation of static fields is first described, and the circuital relations are developed. Div, curl and related vectorial operators are discussed in connexion with Maxwell's equations, and the relations involving the general scalar and vector potentials are then considered. Many applications are given, and there are neat proofs of a number of well-known theorems. In little more than a hundred pages the author develops practically all of the more important mathematical relations of classical electromagnetic theory. A useful table shows the connexion between the relations discussed, and indicates clearly those which are derived directly from experiment.

The last chapter, which is concerned with the Lorentz transformation, gives an admirable introduction to tensor methods, and to the relativistic four-dimensional formulation of the theory.

The book as a whole should be most useful to all those physicists who can appreciate mathematical methods most readily when they are presented in close connexion with physical applications. E. C. S.

Physics for Medical Students. a Supplementary Text Book By J S Rogers Edited by Prof T H Laby Pp x+205 (Melbourne Melbourne University Press, London Oxford University Press, 1933) 11*s* 6*d* net

IT is very desirable that the attention of teachers of physics and medical students, including qualified medical men, should be directed to this book, for it represents the first attempt, so far as the reviewer is aware, to supplement the ordinary textbooks of physics which are given to medical students It is a very successful attempt to show that physics is a science which really does have an intimate connexion with the theory and practise of the art of healing, as well as with the necessities of everyday life Such a book has long been wanted and the author well deserves our congratulations on his achievement

The opening chapters give a brief but very good outline of the history of physics Incidentally, the author follows tradition in ascribing to Davy an experiment with blocks of ice which he never performed, for Davy did not rub pieces of ice together *in vacuo*, he rubbed them together in air, and he recorded an impossible result Later chapters give excellent accounts of osmosis, the colloidal state of matter, ultra-violet light, the microscope, hydrogen ion concentration, high frequency currents and X-rays In all these chapters the importance of physical facts and theories to medicine is stressed, whilst the chapters on blood pressure and its measurement, body temperature, gains and losses of energy in the human body, the resonance theory of hearing, the human eye and the therapeutic uses of radiations also testify to the industry and diligence which the author has so successfully employed in showing that physics can be made interesting to medical students

The book is well printed and illustrated It is very pleasant to read and the manner in which the author has everywhere tabulated and arranged the most striking and important points in each section makes it a handy book of reference There are obvious ways in which the author may expand this work in future editions, and it is to be hoped that it will find an extensive sale in Great Britain

L F. B

Bulletin of the National Research Council No 90 *Physics of the Earth.* 6 *Seismology* Pp viii+223 (Washington, D C National Academy of Sciences, 1933) Paper, 2 dollars, cloth, 2 50 dollars

THIS new "Bulletin" is comprehensive and inexpensive The authors are J B Macelwane, H O Wood, H F Reid, J A Anderson and P. Byerly, all of whom have made distinguished contributions to seismology. They discuss the various theories of the origin of earthquakes, field data, the design of seismographs, the theory of wave propagation, and the interpretation of the results References are abundant up to 1931, and there are a few for 1932, and the authors have evidently read and understood what they quote Two omissions are perhaps worthy of notice The work of Stoneley and Tillotson on surface waves is mentioned without statement of the results they derive for the thicknesses of the layers, and attention might have been paid to the theoretical solution for a sudden disturbance spreading in three dimensions from a small region

The book is not made needlessly long by the inclusion of out-of-date material, but the reviewer is left in doubt as to whether Uller's theory of wave propagation needed exposition Is this very complicated work really able to give any results that cannot be obtained quite easily otherwise? So far as the reviewer can see, it has all the defects of the method of normal modes and none of its virtues But on the whole the book is the most convenient guide to seismology that has yet appeared

H J

Physical Constants Selected for Students By Dr W H J Childs (Methuen's Monographs on Physical Subjects) Pp viii+77 (London Methuen and Co, Ltd, 1934) 2*s* 6*d* net

THIS little volume of physical constants is well designed in many ways to suit the student's pocket It is most convenient in form and size, and its price is so modest that few students will be unable to purchase the book It is sufficiently complete to satisfy practically all the requirements of the ordinary teaching laboratory and most of the normal requirements of a research laboratory

Psychology

Mental Defect By Dr Lionel S Penrose (Text-Books of Social Biology) Pp xi+183+4 plates (London Sidgwick and Jackson, Ltd, 1933) 8*s* 6*d* net

MENTAL defect or more technically, oligophrenia, is such a serious problem that no apology need be made for stressing the extreme importance of educating public opinion So much inaccurate and prejudiced opinion finds its way into print, particularly in the more sensational daily Press, that an effort should be made to combat it Dr Penrose's book is meant for medical or educated lay readers and is therefore not suitable for "the man in the street" He gives an interesting and accurate account of the physical conditions met with in defectives of all classes, and discusses the psychological examination, the taking of family and personal histories, and the classification In discussing mongolism, the writer expresses the opinion that Crookshank's view that the condition is a regression to earlier ancestral types cannot be upheld He does not express an opinion on Clark's view that the condition represents a condition of fœtal hyperthyroidism

It is very gratifying to read a sane account of sterilisation The author points out that only one defective out of twenty is born of defective parents, that many defectives are unlikely to produce children and that it is mostly the high grade ones who are difficult in this way. This of course is exactly the group that are difficult to deal with from a legal point of view In the author's opinion, adequate segregation is a much more rational procedure , sterilisation is no solution of the problem of the mental defective

Psychoanalysis and Medicine a Study of the Wish to Fall Ill By Karin Stephen Pp vi+238 (Cambridge At the University Press, 1933) 8*s* 6*d* net

DR KARIN STEPHEN bases her book upon a series of eight lectures which she delivered mostly to medical students at Cambridge She has an exceptionally good grasp of her subject, and adopts as the basic idea of her book the hypothesis that neurotic symptoms are defences designed to prevent anxiety from developing when repression threatens to give way Dr Stephen is an out-and-out Freudian, but there are many who will find fault with her statement ". if we can argue by analogy from the neuroses to the other group of psychogenic illnesses, the psychoses (insanity) " It is surely doubtful if any psychosis can be looked on as purely psychogenic in origin. The causation of the psychoses is a very complicated and debatable subject, and although psychoanalysis can offer explanations of mechanisms its theories of causation are not so easily applied or accepted by those best qualified to assess their value in an impartial manner

The Human Personality By Dr Louis Berg Pp xv+321 (London . Williams and Norgate, Ltd , 1933) 8*s* 6*d* net.

DR. L BERG looks on the human personality from the *Gestalt* point of view, a conception which has been gradually developing during recent years amongst those best qualified to judge. There is a number of unusually sensible statements in this book—perhaps the most sensible is "We speak of 'problem children' but we should really say problem *parents* " So many problem children are the results of errors of training in the pre-school years It is only expressing the view of one school of thought to say that manic-depressive insanity, dementia præcox and paranoia are functional diseases These disorders are not necessarily due to psychic wounds Kretschmer's rigid views as to the development of cyclothymia in pyknics and dementia præcox in asthenic types have recently had considerable doubt cast upon them and we should adopt an attitude towards them of 'not proven' To say that "schizoids become insane because of psychic wounds such as sorrow, unhappy love affairs or career failures" is using symptoms to explain causation

The Way of all Women a Psychological Interpretation. By Dr M. Esther Harding Pp xv+335 (London, New York and Toronto Longmans, Green and Co , Ltd , 1933.) 15*s* net

IT is an arguable question whether the roots of disorders of conduct and life difficulties are not deeper than can be reached by reading a book, however good it may be. Dr Harding has attempted to explain many difficulties of life, but whether her explanation would be accepted or not by the neurotic and those in difficulties is another matter The unconscious has an unfortunate habit of erecting barriers against the very explanations given, and a prolonged analysis is often necessary to get behind these barriers and adjust the mind in difficulties to its difficulties Apart from this, however, the book contains a wealth of sound advice, and there can be few who, having read it, will not derive benefit if they apply the theory to their practice.

Inner Conversion in X-Ray Spectra

MORE than ten years ago, Coster[1] reported that he had carried out experiments with heavy elements for tracing X-ray characteristic lines due to the transition $L_1(2s) \leftarrow L_{2,3}$ $(2P_{1/2}, {}^2P_{3/2})$, but got no positive results During the last ten years, a number of other investigators[2] have also reported negative results

These failures have remained rather mysterious for the transition $L_1 \leftarrow L_{2,3}$ ($\Delta n = 0$) is not forbidden by quantum mechanics and actual calculation based on wave mechanics shows that the expected line should be quite intense A recent search by one of us (J B M) for the expected line of W ($L_1 - L_3$, $\nu/R = 139\ 5$, $\lambda = 6\ 4$ A) also yielded no positive result though both the excitation and exposure were more than sufficient A search into the current literature shows that though these lines ($L_1 \leftarrow L_3$) have not been obtained, a number of lines of heavy elements (73 Ta to 81 Tl) due to the transitions between N levels ($N_{4,5} \leftarrow N_{6,7}$) have been obtained by Thibaud[3], del Rosario[4], Magnusson[5], Prins and Takens[6], while the last two workers report lines due to the transitions ($M_{2,3} \leftarrow M_{4,5}$) of a number of elements Since in all these lines, $\Delta n = 0$, the failure to obtain the lines due to the transition ($L_1 \leftarrow L_3$) was remarkable

It appears to us that the failure to obtain the ($L_1 \leftarrow L_3$) line is to be completely ascribed to the inner conversion of such lines in the M levels of the elements A scrutiny of the L level values of the elements shows that from 92 U to 68 Er the ($L_1 - L_3$) values are greater and very close to the M level values; for example, in W, the ν/R value for ($L_1 - L_3$) is equal to 139 5 while $M_4 = 137\ 5$, $M_5 = 132\ 9$

An application of a modified form of the formula for inner conversion given by Miss Swirles, Taylor and Mott, and Hulme[7] shows that the ($L_1 - L_3$) lines should be completely converted in such cases It is only in 68 Er that the ($L_1 - L_3$) ν/R value is just less than any of the M-level values and much larger than N-level values But this situation persists only up to 55 Cs, from iodine again, $L_1 - L_3$ becomes just larger than some M-values, so that it is expected that only elements from Er to Cs are capable of showing lines due to ($L_1 \leftarrow L_3$) transitions This conclusion has not yet been tested

It appears that the phenomenon of inner conversion is responsible for many of the intensity anomalies which are observed in the line spectra of X-rays, as was suggested some years ago by Wentzel.

Disintegration of the Separated Isotopes of Lithium by Protons and by Heavy Hydrogen

THE two known isotopes, Li^6 and Li^7, have been separated in quantities of the order of one microgram by two separate methods depending on the passage of several microamperes of lithium ions through electric and magnetic fields The separate isotopes were collected on metal discs cooled with liquid nitrogen, and after fixation by exposure to hydrochloric acid gas, were bombarded by protons and by diplons in an apparatus already described[1] It was possible to observe several hundred disintegration particles each minute from the Li^7 targets and about half that number from the Li^6 targets arranged to contain about the same number of atoms The results are summarised in the accompanying table

Bombarding Particles	Lithium 6	Lithium 7
Protons	α particles of 11 5 mm range	α particles of 8 4 cm range
Diplons	α-particles of 13 2 cm range	α-particles up to 8 cm range
	Protons of 30 cm range	Neutrons

The purity of the separate samples was apparent from the very small number (less than 1 per cent) of the 8 4 cm particles obtained from the Li^6 target, and the total absence of 13 2 cm particles from the Li^7 target

It may be seen from the table that observations have been made not only on the α particles but also on the protons and neutrons liberated from lithium by heavy hydrogen Owing to the absence of the much more abundant Li^7, the Li^6 targets show very clearly the presence of the very definite range of doubly charged particles previously reported[1] at 11 5 mm The mica window through which the particles escaped into the detecting chamber had an absorption equivalent to 6 mm of air, so that the origin of the shorter 7 5 mm range group also found previously could not be determined

These observations are in complete accord with the assumptions made in previous papers[1] Details of the isotope separation will be published elsewhere

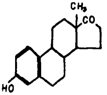
Dehydrogenation of Œstrin

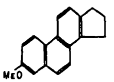
THE chemical constitutions of ketohydroxyœstrin and trihydroxyœstrin are now largely established, mainly by the investigations of Butenandt, Marrian, and their collaborators There remain, however, certain features of the molecular structure which have not yet been experimentally proved, but depend upon the assumption that the hormones are biological degradation products of cholesterol The experiment now recorded was undertaken as a preliminary step in an attempt to obtain confirmation of some of the structural details which are still in doubt

Although Butenandt[1] has shown that trihydroxyœstrin may be transformed into 1 . 2-dimethylphenanthrene by selenium dehydrogenation of the dicarboxylic acid arising by fission of the five-membered ring IV, the dehydrogenation of the hormone itself, with the tetracyclic system still intact, has given very unsatisfactory results. The only pure substance which has been obtained hitherto is chrysene (0 0049 gm from 5 4 gm of crude crystalline hormone), which was isolated by Butenandt and Thompson[2] from the products of zinc dust distillation of ketohydroxyœstrin Nevertheless, it is clear from recent work on the selenium dehydrogenation of polycyclic compounds of known structure containing five membered rings (for example, Cook and Hewett[3]) that suitable œstrin derivatives ought to be capable of smooth conversion into derivatives of a *cyclo*-pentenophenanthrene by this method

This is, in fact, the case In order to avoid complications due to substituents in the five-membered ring, the carbonyl group of ketohydroxyœstrin was first reduced to a methylene group (Kishner-Wolff method) Dehydrogenation of the 'desoxo' compound so formed led to a non-acidic substance by some secondary change involving the hydroxyl group In the remainder of the material (0 75 gm) the hydroxyl group was therefore methylated before dehydrogenation The resulting methoxy compound (m p 76°–77°; Butenandt[4] gives 72°) was heated with selenium at 300°–320° for 24 hours, the product was distilled over sodium in a high vacuum, and the distillate was finally recrystallised from alcohol There was obtained 0 125 gm of colourless needles or plates (depending on the conditions of crystallisation), which gave analytical figures in good agreement with those required for a methoxy-*cyclo*pentenophenanthrene (Found C, 86 9, 86 95 ; H, 6 2, 6 4 , OMe, 12 1 per cent Mol wt , 264, 268. $C_{18}H_{16}O$ requires C, 87 05 , H, 6 5 , OMe, 12 5 per cent Mol wt , 248) This substance gave an orange-red picrate, m p 135°–136 5° (Found C, 60 8 ; H, 4 0 $C_{24}H_{19}O_8N_3$ requires C, 60 4 , H, 4 0 per cent), and a golden-orange trinitrobenzene complex, m p 160°-161° (Found · C, 62 5, H, 4 2 $C_{24}H_{19}O_7N_3$ requires C, 62 4 , H, 4 15 per cent) The melting point (134 5°-136°) of the methoxy compound was unaltered by purification through the trinitrobenzene complex



(I)



(II)

If the phenolic hydroxyl group and the five-membered ring are correctly placed in the current formula for ketohydroxyœstrin (I), then this product of dehydrogenation must be 7-methoxy-1 2-*cyclo*-pentenophenanthrene (II) The synthesis of (II) is in progress (in collaboration with Dr A Cohen and Mr C L Hewett) by a modification of the method used for the synthesis of the parent hydrocarbon, 1 2-*cyclo*pentenophenanthrene[3]

Influence of Sensitisers on Chemical Reactions produced by Gamma Radiation

ATTENTION was first directed to the above subject during the course of an investigation on the decomposition of chloroform by radiation from radon. Chloroform is decomposed with liberation of chlorine which slowly disappears with formation of hydrochloric acid as a secondary product. The decomposition was measured by estimating the chlorine set free Certain discrepancies were obtained in the results which were largely explained when it was found that the apparent rate of decomposition was greatly influenced by the presence of the products formed This was shown by irradiating for a second time the chloroform containing small quantities of products from the first irradiation It has been demonstrated by others that traces of moisture considerably increase the decomposition of chloroform by X-radiation

Gamma radiation oxidises solutions of ferrous salts. Berthelot's solution of ferric chloride and oxalic acid, which is rapidly reduced by ultra-violet light, was found not to be reduced at all by gamma rays On the contrary, the iron in the reduced solution is oxidised to the ferric state, and the addition of small quantities of various organic and inorganic substances was found to accelerate or retard the rate of oxidation Striking results have been obtained recently with the photographic salt, potassium metabisulphite Solutions of this substance oxidise slowly in air, but more rapidly when irradiated The solutions used were of such strength that 5 c c required approximately 18 c c. *N*/1000 iodine solution for titration The radon seed (150–250 millicuries in strength) was enclosed in a lead case with walls 1 mm thick, and was held centrally in a glass tube, surrounded by 15 c c. of solution contained in a larger glass tube Two tubes of solution without radon served as controls Overnight the controls showed an amount of oxidation in 5 c c equivalent to approximately 1 c c *N*/1000 iodine The excess oxidation with radiation varied from about 2·5 to 6 c c *N*/1000 iodine

Addition of small quantities of iodine solution to the bisulphite had a negligible effect on the oxidation of the non irradiated controls, but a very great effect on the solutions irradiated, so much so that 0 04 c c. of *N*/1000 iodine added to 100 c c. of the bisulphite solution was sufficient under the prescribed conditions to bring about the complete oxidation of the irradiated solution. Potassium iodide and potassium bisulphate, added in equivalent amounts, produced the same effect Light and X rays also bring about the oxidation of bisulphite, but in the case of these radiations the sensitising action of irradiation is less marked than with gamma radiation. Glutathione, an organic compound of great importance in tissue metabolism, was prepared by Hopkins' method and tested. Although its rate of oxidation in solution was quite definitely accelerated by gamma radiation especially in the unneutralised state, the rate was not further increased by iodine, potassium iodide or potassium iodate

Crabtree and Cramer, in recent communications dealing with the action of radium on cancer cells[1], have shown that the susceptibility of cells to radium is not a fixed property of a given type of cancer cell, but changes with the environment. The effect of certain well-known inhibitors of metabolism was shown to produce varying sensibility to radium in tumour cells Prussic acid and low temperature greatly increased the susceptibility of tumour tissue to radium, anaerobiosis produced the opposite effect. The glycolytic inhibitors iodoacetic acid and sodium fluoride had little or no effect on the action of radium As a result of their experiments they suggest that it may be possible to increase the radiosensitivity of cells by introducing suitable chemical substances The results obtained in our laboratory appear to lend force to this suggestion by showing that reactions fostered by gamma-, and X-, radiations can be sensitised by small additions of chemical bodies in an analogous manner to the action of sensitisers in many well known photochemical reactions.

Ethane from Acetic Acid

I SUGGEST that Messrs Glasstone and Hickling (NATURE, Feb 3, p 177) may spare themselves from any "comprehensive investigation of the Kolbe synthesis" This was made clear nigh on fifty years ago

Chemists were rational in the distant past Having proved experimentally, by their joint labours, in 1847–48, the truth of the conception first propounded by Berzelius, that acetic acid was "a compound of oxalic acid with the conjunct methyl", our view to-day, Frankland and Kolbe both started out as Japheths in search of Radicles Frankland went gaily off with the alcoholic iodides and metals, to bag zinc methyl and various paraffins Kolbe resorted to electrolysis but also bagged paraffins His results are recorded in the *Quarterly Journal of the Chemical Society*, vol. 2, the account was given to the Society on March 29, 1849, before anything had been heard of Kekulé.

From previous experience, regarding 'electrolysed oxygen (as) one of the most valuable oxidising agents at the chemist's disposal", thinking that "electricity might effect a separation of its conjugated constituents" Kolbe electrolysed acetic acid (as potassic salt) He obtained the result he expected, expressed in the equation

$$HO\,(C_2H_3)C_2O_3 + O = C_2H_3 + 2CO_2 + HO.$$

Kolbe's use of CO_2 (C = 6, O = 8) is of historical significance. Acids were then thought of as compounds of an acidic with a basic oxide; bearing this in mind, the equation we write to-day is the precise equivalent of Kolbe's

$$2CH_3\,CO_2H + O = (CH_3)_2 + 2CO_2 + OH_2.$$

Came 1865 Schutzenberger, following up Sir Benjamin Brodie's discovery of acetic peroxide, simply mixed an excess of barium peroxide with acetic oxide in a small flask; on warming the mixture, ethane, together with twice its volume of carbon dioxide, was regularly evolved He remarks "the preparation of ethane in this way is as simple as that of any other gas" The work has been strangely overlooked (*C.R.*, 61, 487; 1865)

Some of us, having regard for patent facts, have long preached the doctrine, that the electrolysis of aqueous solutions is essentially an oxidation (hydroxylation) process Oxygen is commonly obtained because the peroxide first formed is decomposed at the electrode surface Any promoter of its breakdown, such as lead peroxide, necessarily prevents the appearance of the peroxide or of its immediate decomposition products In making acetic acid from aldehyde, on the large scale, during the War, the need of a manganese or other suitable salt to promote decomposition of peracetic compounds was clearly recognised, though not fully until after a serious explosion Textbooks have little regard for truth The fiction that hydrogen and oxygen are immediate products of electrolysis is a hardy chestnut we might well transfer to the dustbin no boy should be taught to use it as a Conqueror

HENRY E ARMSTRONG

Passage of Hydrogen through Steel

I WAS much interested in the communication by T N MORRIS to NATURE of February 10, p 217, concerning the observations he has made relating to the diffusion of hydrogen through steel Since he asks whether facts of the kind he mentions have been previously recorded, may I make the following observations ?

The diffusion of hydrogen through mild steel under varying conditions of temperature and acid concentration formed the subject of a paper which was published (under my name) in the *Journal of the Iron and Steel Institute*, vol 2, 1925 This paper dealt with a quantitative study of certain aspects of this interesting problem, but it was by no means the first time that the phenomenon had been observed So far back as 1874, Osborne Reynolds directed attention to it in a paper he published in the *Memoirs and Proceedings of the Manchester Literary and Philosophical Society*, vol 13, p 93

Side-Chain Reactions of Benzene Derivatives

WE have recently examined a number of side-chain reactions in the light of the postulate that the differences in the rates of reaction of a series of similarly constituted compounds under identical conditions are to be ascribed solely to different energies of activation, substituents contributing additively to the total energy[1] Our results[2] for the reaction of hydrogen ion with various *p*-substituted acetophenones $X\,C_6H_4\,CO\,CH_2R$ (acid-catalysed prototropy) indicate that the energies of activation are given by the expression $E = E_0 - C\,(\mu - a\mu^2)$, where C and a are constants for the series, E_0 is the value of E for the unsubstituted compound, and μ is the dipole moment of C_6H_5X. The substituents dealt with included three halogens, to which the equation applies accurately, but did not include 'inclined' groups such as $-$OAlk and $-NAlk_2$ We further suggested[3] that the expression $E = E_0 \pm C\,(\mu - a\mu^2)$ might be applicable to side-chain reactions in general, the negative and positive signs referring respectively to those of Classes A and B[4] A review of fourteen reactions led us to the conclusion that, for *m*-substituted compounds, the equation is valid except when the substituent is a halogen, while, with the substituent in the *p*-position, complications arise, as anticipated, from the operation of electromeric effects, and in a number of Class *B* reactions the term in μ^2 changes sign, an observation for which there was no obvious explanation.

We wish now to suggest that, while the equation $E=E_0-C(\mu-a\mu^2)$ applies to reactions of Class *A*, the correct expression for Class *B* reactions may be $E=E_0+C(\mu+a\mu^2)$. Assuming this expression, the halogens *as a group* behave in accordance with the dipole moments of C_6H_5X, while the 'inclined' groups are exceptional. The new view is based, in fact, on the probability (kindly pointed out to us by Prof. Ingold) that the 'effective polarity' of these groups is represented not by the measured dipole moment but by the component in the plane of the nucleus. The calculation of the angle of inclination for $-OCH_3$, from results where complications appear to be absent[5], gives the value 112° or 104.5°, according as the value of μ for anisole is taken as -0.8 or -1.2 Debye units. This may be compared with the angle suggested for singly-linked oxygen[6] and the vertical angle for water[7].

No clear distinction can at present be drawn between the possibility outlined above and that suggested previously, but it is hoped to obtain further information from experiments now proceeding at these laboratories.

The Infinite and Eternal Energy

THE quotation for which Mr. Donald Murray asks in NATURE of February 24 is in Herbert Spencer's "Principles of Sociology", Part 6—Ecclesiastical Institutions, Chap. 16—Religious Retrospect and Prospect. It there reads as follows: "But one truth must grow ever clearer—the truth that there is an Inscrutable Existence everywhere manifested, to which he [the man of science] can neither find nor conceive either beginning or end. Amid the mysteries which become the more mysterious the more they are thought about, there will remain the one absolute certainty, that he is ever in presence of an Infinite and Eternal Energy, from which all things proceed."

It first appeared in January 1884, when this chapter of the 'Sociology' was published as the first article in the *Nineteenth Century*. It was, I think, mainly responsible for the attack made upon Spencer by the late Mr. Frederic Harrison, the controversy between him and Spencer lasting almost throughout that year. In the course of the controversy, Mr. Harrison had referred to the Inscrutable Power as "the All-Nothingness", and Spencer replied in July: "So far from regarding that which transcends phenomena as the 'All-Nothingness', I regard it as the All-Being. Everywhere I have spoken of the Unknowable as the Ultimate Reality—the sole existence; all things present to consciousness being but shows of it." The entire controversy was issued in book form in America, at the insistent request of Spencer's American friend Prof. E. L. Yeomans, but an objection raised by Mr. Harrison so incensed Spencer that he wired to his New York publishers ordering the book to be withdrawn and the plates to be destroyed. It was unfortunate, for the whole incident made much clearer the positive aspect of Spencer's doctrine concerning the Ultimate Cause, as opposed to the negative aspect so unduly enlarged upon by his opponents.

[Several other correspondents, for whose letters we cannot find space, have also identified the quotation.—Ed. NATURE.]

Uniformity in Bibliographic Particulars

IN the library of the John Innes Institution, and presumably in other scientific libraries, the indexing of 'separates' has become a formidable task. It is made more laborious where the particulars given of the source of the paper are misleading or incomplete. Editors will not, I am sure, be unwilling to consider the needs of the librarian, and I therefore venture on some suggestions.

First, the bibliographical particulars should be readily available on the cover or front page of the separate. (It is not necessarily the business of the person making the index cards to read the papers.) Secondly, no irrelevant matter should appear. The citation should be essentially as follows:

> Name of author, title of paper, year, name of journal, volume, page references. (The pagination should be unaltered.)

Although there are a number of journals which adhere to this standard practice, too many others deviate from it in one way or another. The most usual deviations are the following:—

(1) Separates are sent out in blank covers, or in covers bearing the name of the journal but no other particulars.

(2) The title, etc., is given on the cover, but the page references omitted.

(3) The name of the journal is followed by the day, month and year of publication, and the volume and page references omitted, or the session (in the case of *Proceedings*) is given, and the year omitted.

(4) The paper is re-paginated, and the original page references not only omitted but also unascertainable.

(5) The cover is like that of the parent journal, and the name of the author of the paper either has to compete with that of the editor of the journal, or does not appear on the front page at all.

To take these points in order: (1) may be due to economy, which does not permit of a separately printed cover. It would cost no more and would suit most of us better to have such a paper without a cover, but with full particulars at the head of the first page. (2) is due to lack of foresight, as it is scarcely any more trouble for the printer to add the page references when printing the title, but in their absence *every* recipient of the separate who keeps a card-index has to waste time looking inside. (3) shows a lack of foresight that is even more depressing, as one cannot cite the complete reference without undertaking bibliographical research on one's own account. As the reprints are meant to reach those who do not see the journal, it seems indeed thoughtless to give on them a citation which cannot be completed except by reference to a file of the journal. The same applies to (4). In (5), which is due to excess of zeal, the author's name if it appears at all is coyly hidden between those of the editor and publisher (as in the case of the railway station which was called Bovril). This at the best is distracting to the eye, at the worst, in the hands of an assistant who is not very strong in foreign languages, it can lead to quite remarkable results in the filing.

Thirdly, on the more general question of bibliography, apart from the immediate one of separates, journals have various idiosyncrasies. There are for example some which begin over again at p. 1 for each part within the volume, or have separately paginated appendices. Surely the volume should always be the unit. There is one venerable and distinguished London journal sent out in continuously numbered parts, the volumes are made up of an irregular number of these parts, but there is nothing on the cover to show which part begins or ends a volume. Then there are a great many journals which still use roman numerals, a quaint but eye-straining practice. There is the confusing trick of numbering the plates, including their versos which are always blank, along with the text, and finally there is the practice of putting last year's date on an overdue part. Such falsification of a document is scarcely an example of scientific integrity.

To conclude, it is evident that many journals which are scientific in content are traditional in form. It may be that there are certain advantages, of which I am unaware, in the practices which I deprecate, but it seems more likely that they have persisted, not on account of any essential virtue, but simply because it has been no one's business to have them altered. The eminent men of science who conduct the journals may consider such small matters unworthy of their attention, but convenience and consistency underlie all scientific method and might well be applied in this case as in others.

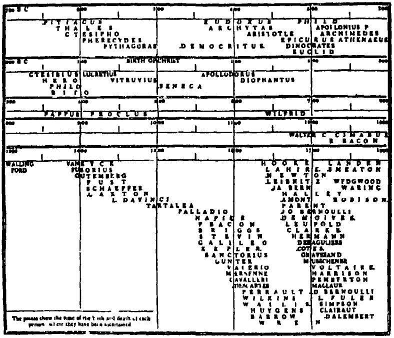
Graphical Determination of Contemporaries

THE illustration which Mr. Lucas gives of his graphical determination of contemporaries[1] is perhaps an unfortunate one, for even with the help of this example his letter affords no clue as to what he is trying to do or why he has chosen an oblique method of doing it.

The duration of a life is very simply represented by the length of a line or, better still perhaps, by the interval between two points and it would seem that the interesting chronologies[2] of Prof. Thomas Young are admirably adapted to the determination of contemporaries.



The points show the time of the birth and death of each person where they have been ascertained

FIG. 1.

In referring to the Chronology of Mathematicians and Mechanics, reproduced in Fig. 1, I was interested to read, on the facing page, Young's counsel of perfection to everyone who is desirous of enlarging the sphere of our knowledge with respect to any branch of science "to collect that previous knowledge of all that has been already done with the same view, which, in justice to himself, he ought to acquire before he enters on the pursuit, or at any rate, in justice to the public, before he calls on the world at large to participate in his improvements and discoveries".

The Viability of Spirochætes dried in Vacuo

IT is well known that all kinds of spirochætes, both pathogenic and non-pathogenic, are unable to withstand ordinary desiccation, for repeated experiments have shown that they very soon lose their vitality after ordinary drying. Hitherto, however, no attempts seem to have been recorded on the results of drying these organisms by the special methods used with success for the preservation of certain filterable viruses and some bacteria. In view of the difficulty and expense of maintaining strains of spirochætes in the laboratory, it seemed of interest to see whether they could be preserved in the same way, and the results show that under special conditions it is possible to dry them without destroying their vitality.

---

[1] NATURE, 133, 141, Jan. 27, 1934.

[2] Young, T., 'A Course of Lectures on Natural Philosophy and the Mechanical Arts', London, 1807.

Five strains of spirochætes have been used in these preliminary experiments, two culture strains of *Spirochæta pallida* obtained respectively from Kroo and Vasarhelyi, and three strains of *Spirochæta biflexa*, the common water leptospira, two Leyden strains obtained from Schuffner and van Theil, and a strain which I have recently isolated from London sewage. Extremes types of spirochætes were thus included, for *Spirochæta pallida* is somewhat exacting in its cultural requirements and in addition to being very susceptible to variations in the media, normally requires subculturing every week, whilst *Spirochæta biflexa* is much more resistant and, at room temperature, cultures will remain positive for some months

About 0 5 c c of a rich suspension of the spirochætes in their respective media, which both contained approximately 10 per cent of rabbit serum, was placed in each of a number of small sterile test-tubes. The tubes were then placed in a freezing mixture at −10° C until the contents had solidified, and then placed in a desiccator containing phosphorus pentoxide, and the air exhausted as quickly as possible The desiccator and its contents were then left in the ice chest and the desiccating agent renewed the following day and the air again exhausted After 15 days under these conditions, the dried contents of the tubes were inoculated into fresh culture media, and in every case the spirochætes were found to have remained alive The strains of *Spirochæta biflexa* seemed to grow more slowly than when ordinary motile spirochætes were used for inoculating the culture tubes, but in the case of the two strains of *Spirochæta pallida*, their rate of growth seemed to have been unaffected

Although at present the vitality of these spirochætes dried *in vacuo* has only been tested up to 15 days, there is no reason to doubt that they will remain alive for very much longer periods This method, therefore, should be of value for the maintenance of strains of spirochætes in the laboratory, as it reduces the necessity for repeated subculturing

Insect Transmission of Spike Disease

IT has been recently announced[1] that transmission experiments with the Jassid, *Moonia albimaculata*, have yielded three positive results; that the symptoms so produced are inseparable from typically spiked plants on morphological, biochemical and cytological grounds

This important result was the subject of a discussion at one of the meetings of the Working Committee on Spike-Disease Investigation (July 28, 1933) when Dr V Subrahmanyan, in view of the fundamental nature of the finding, suggested that the result should be critically examined in all its aspects As a result of the discussion, it was felt that the evidence, based on symptomatic and other grounds, was by itself not sufficiently conclusive to justify the incrimination of *Moonia* as the vector of spike disease. It was therefore suggested that the matter should be regarded as *sub judice* pending the results of infectivity experiments by grafting, which was considered to be the decisive test in doubtful cases of disease.

It is well known that the sandal plant assumes a variety of morphological characteristics, some of which are often mistaken for the condition of spike. Experiments have shown that this condition can be brought on by deprival of host plants, an impoverished soil, drought and other adverse soil and climatic factors These symptoms can be distinguished from those of a genuinely spiked plant, are not transmitted to other healthy plants by grafting and can be made to disappear when the adverse conditions are removed

A typical spiked plant, however, is infective, the symptoms of the disease being communicable to other healthy plants through grafting, a technique which has proved most useful in determining the infectivity of doubtful cases of spike. It is the infectious character of the disease that renders the problem economically important and serious

It is clear from the above discussion that it is important to distinguish between the curable and non-infectious condition of stunting induced by an adverse environment, as against the deadly and infectious condition of spike disease, which, to an experienced worker, is not difficult to diagnose The following are results of grafting tests which have been carried out.

Leaves from	Number of plants operated	Number of plants spiked
Spiked plants	12	9
Insectary plants	14	0

They confirm the suspicion that the three plants alleged to be diseased only represented a stunted condition which was brought on by an impoverished soil, want of a vigorous host and probably aggravated by insect feeding The symptoms have not been transmitted through grafting, and further, the plants themselves, after a careful nursing with fresh soil and host, have since turned completely healthy

Bilateral Gynandromorphism in Feathers

MR PAUL 'ESPINASSE has recently pointed out[1] some difficulties preventing complete acceptance of the growth rate theory of Lillie and Juhn[2] in which bilateral gynandromorphism of individual feathers is supposedly explained. The existence of differences in rates of growth of individual barbs, by which these authors explain different degrees of susceptibility to female hormone, would be proved if, in successive cross sections of a feather, barbs arising near the ventral point fused with the rhachis at a higher level on one side than on the other, but this has never yet been observed

The concrescence theory of development of a feather, in which the rhachis is regarded as formed from two halves of a collar (the growing basal region) is also due to these authors, but this interpretation, necessary for an explanation of the growth rate theory of Lillie and Juhn, is not in agreement with the results of Davies[3] and Strong[4].

According to the present investigation, the formation of ridges in a feather follows, and is probably due to, the rapid proliferation of intermediate cells causing increased pressure on the pulp, while lateral expansion is prevented by the sheath Those ridges proceed in a curve round the feather germ, so that ultimately the ridge nearest the ventral point lies dorsally There is no suggestion of a movement of cells from one position to the other --rather a passive cutting up of the intermediate cell layer

The rhachis has a complex origin, as Davies and Strong agree, but which Lillie and Juhn consider incorrect Sections through the tip of a feather show a ring of barbs, with little or no difference in size between the ventral and dorsal ones This is particularly evident in embryonic feathers Successive cross sections down the feather show the fusion of barbs to form the rhachis

The hyporhachis is formed in the same way, the ridge nearest to the ventral point fusing with its neighbour as do the ridges near the dorsal point in forming the rhachis The calamus is merely the cornified collar, as though the process of cornification, having gained speed in passing down the feather (correlated doubtless with the withdrawal of pulp) is here too rapid for the formation of ridges

In view of this method of development of individual barbs, it is difficult to correlate the appearance of female bars on one side only of an otherwise symmetrical feather, with differences in growth rate of the barbs Barbs certainly grow more quickly at their apices, where they are smaller in cross section than near the rhachis—hence the upward curve of barbs in a definitive feather. But barbs of equal length at any level must of necessity have arisen at the same time near the ventral side of the germ Some other explanation, therefore, must be advanced for a correct interpretation of the female bar in the feathers figured (Nos. 51 and 52) by Lillie and Juhn

A re-examination of feather development is obviously necessary for an accurate explanation of known experimental facts, and it is hoped, during the summer, to publish the results of a study, now nearing completion, of the development of nestling and definitive feathers in the domestic fowl and the duck, and of definitive feathers in the starling

Effect of Yeast Extract on the Growth of Plants

WE have read with great interest the communication by Prof V Subrahmanyan and G. S. Siddappa in NATURE[1] under this title, in which the authors state that in 1932–33 several Indian papers published results of their experiments, in which yeast extract was injected into plants with a marked effect on the growth and blooming. Unfortunately, we were hitherto completely unacquainted with this interesting work and, consequently, were unable to refer to it in our previous paper on the subject[2].

Our work was carried out in 1932–33, and differs substantially from the observations of Subrahmanyan and Siddappa, as we showed that plants are able to take up the promoting factor (or factors) in the yeast extract, through their roots. In our opinion, this is of great interest, since it tends to show that the micro-organisms in soil are of importance in the formation of different growth-promoting factors Soil micro-organisms would thus have functions previously unforeseen.

Further to our earlier note, we have found that the factor which stimulates the blooming of the pea is soluble in ether (communication to a meeting of the Society of Finnish Chemists on November 4 last) The extract is equally effective in sterile water cultures and in the usual pot cultures with quartz sand

Pot cultures with different types of soil showed that in clay soil the effect of yeast extract on the growth of the pea was still distinct, although not so marked as in quartz sand. In rich humus soil the effect was very weak or possibly nil This could be explained by assuming that the stimulating factor of yeast extract is normally present in soils rich in organic matter and with an abundant microflora

A detailed report of our work on the subject will appear elsewhere

The Age of the Sub-Crag Implements

I AM glad that Prof Boswell[1] has expressed an opinion upon the nature of the material attached to the surfaces of a rostrocarinate flint implement exhibited, recently, in the British Museum There are few people for whose views upon such a matter I entertain more respect, and I intend, if he will allow me, to go further into the question of this particular implement with him, and of that of others I am in process of collecting from beneath the Red Crag It is evident that we are dealing with a complex matter in which Prof Boswell's specialised knowledge of Crag deposits will be of great value

As regards the geological age of the boxstones, I find that Lankester, who made a very close study of these specimens, and, in fact, gave to them their characteristic name, states[2] that they are "The Remains of a Pliocene deposit, anterior to the Coralline Crag, and identified by its fossils with the Black Crag, or Diestian Sands of Belgium", while in Clement Reid's "Pliocene Deposits of Britain", p 223, the "Sables à *Isocardia Cor*, or Diestian" of Belgium, are placed by him in what he calls the "Older Pliocene" Also, in the Survey Memoir "The Geology of the Country around Woodbridge, Felixstowe and Orford", p. 16, Prof Boswell himself states "Although the boxstone fauna has been compared with the Continental Miocene, or even with the Oligocene (Rupelian), it is at present generally regarded as of Lower Pliocene Age" It was for these reasons that, in my recent note in NATURE[3], I stated that the Diestian boxstones are referable to the Lower Pliocene epoch But, in the note mentioned, I made no claim that the British representatives of the Continental Diestian deposits are the boxstones of Suffolk. I merely, like Lankester, look upon the boxstones as representing, in the Suffolk Bone Bed, the Diestian Sands of Belgium.

Research Items

Indian Iconography. Tours of inspection in Bengal districts by Mr. H. E. Stapleton, Director of Public Instruction, N. Chakravarti and S. K. Saraswati, have produced data of historical and archæological interest which are recorded in three communications (*J. and Proc. Asiat. Soc. Bengal*, New Ser., 28, No. 1, 1932). In the district of Dinâjpur along the Chirâmati River, in particular, Mr. Saraswati found interesting sculptures among figures worshipped at local shrines which have furnished details of importance in Hindu iconography. In the village shrine of Dohâbandh was found a sandstone *lingam* of very rare iconographic character. It is encircled by four effigies of the Devî, which have matted hair and are seated in the *padmâsana* attitude with clasped hands held up in adoration. The female figures around Siva's symbol evidently stand for his female energies. At Mahendra a previously unknown iconographic specimen was obtained. This is an image, probably of Sûryya, on the pedestal of which are the seven horses and the chariot; above are all the usual attendants, Dandî, Pîngala, his two queens, etc. All the figures are booted as is usual with the image of Sûryya. The interesting feature is that Sûryya has six hands instead of four or the more usual two. The two main hands hold lotuses by the stalks as prescribed, the others show respectively the gestures of 'granting boons' and 'granting security', one holds the rosary and another the pot. Nowhere are six hands mentioned or shown, nor are the rosary and pot known as his attributes. The image seems to correspond to a description of Dhâtri, the first Âditya, except for the two additional hands. This is perhaps the first iconographic treatment of such a deity yet discovered. At Betnâ a female figure fighting with a host of pot-bellied Asuras is evidently an aspect of Chandikâ fighting the demons. She holds various weapons in thirty-two hands, but in spite of the large number of additional arms, the figure is masterful in its life and reality.

Prehistoric Goats of Poland. In a neolithic settlement in the commune of Zlota, Poland (dated 2500–2000 B.C.) remains of domestic goats have been found, and M. K. Wodzicki identifies the fragments as belonging to the *Capra prisca* type (*Acad. Polonaise Sci. Lettres*, 1933, p. 89). The skulls and horns show a considerable amount of variation, but there is no indication that any other species was domesticated. Fragments which have been described from fifteenth and sixteenth century settlements in Poland and from early historic sites also belong to *C. prisca*-typus, although in the Middle Ages two races can be distinguished by the compactness or divergence of the horns, and in the early ages the horns are distinctly smaller and their slope markedly divergent.

Hydrography of an Indian Tank. Dr. Hem Singh Pruthi has made a detailed study lasting over three years of the seasonal changes in the physical and chemical conditions of the waters of the tank in the Indian Museum compound ("Studies on the Bionomics of Fresh-waters in India (1)", *Internat. Rev. Hydrobiol. Hydrographie*, 28, Hft. 1–2, 1932). In the tropics, growth is more rapid and decay is more sudden than in temperate regions; also, because of the great amount of evaporation and consequent rainstorms, the condition of tropical waters is altered more in a few hours than in many days in temperate regions. It was found that there was a complete mixing of surface and bottom waters in January, the upper layers after this becoming warmer and a thermal stratification beginning which is complete in April. The *p*H value has two maxima in the year, in spring and in autumn, the latter being higher than the former. The changes in the *p*H value seem to be connected with the photosynthetic activity of the chlorophyll-bearing organisms, which depends on the weather and the amount of necessary salts available. If the weather is fair, the surface water is generally saturated with oxygen after 10 a.m., but the bottom water is always deficient in oxygen. The surface layers are replenished in salt content partly when the thermal stratification is disturbed during the monsoon or when the waters mix in January, but chiefly by the rain-water laden with salts which flows into the tank from the high banks during the rainy season.

Morphology of the Insect Abdomen. The writings of Mr. R. E. Snodgrass on insect morphology are well known to all students of entomology. In his most recent contribution entitled "Morphology of the Insect Abdomen" (*Smithsonian Misc. Coll.*, 89, No. 8; Oct. 1933) he continues his previous memoir on this subject and, in the present instance, deals with the genital ducts and the ovipositor. He concludes that the primitive gonoducts were paired mesodermal tubes each opening to the exterior by a separate pore. These pores were located on the 7th abdominal segment in the female and on the 10th segment in the male. In most insects, as we know them to-day, a median ectodermal passage has developed and become connected with the primitive ducts. This has resulted in the acquisition of a single genital pore which opens between the 9th and 10th segments in the male, while in the female it is more variable in position since it may be located on the 7th, 8th or 9th segments. In dealing with the structure of the ovipositor, Mr. Snodgrass's account is illustrated by a wealth of original figures portraying the structure of the organ and its associated musculature in different groups. While in many Orthoptera the ovipositor is formed by three pairs of valvules, in the Gryllidæ and Acrididæ only two pairs are evident, namely, the 1st and 3rd, the 2nd pair of valvules being vestigial. On the other hand, in the Thysanura, Hemiptera and Homoptera, the ovipositor is likewise formed of two pairs of valvules, but in these cases it is the 1st and 2nd pairs that compose the organ. The memoir is too detailed to allow of more than brief mention and is one of general interest to students of insect morphology.

Protein Metabolism in Wheat in Relation to Nitrogen Supply. In a study of the distribution of nitrogen in wheat plants grown in water culture, A. G. McCalla (*Canadian J. Res.*, 9, 542, 1933) finds that altering the nitrogen supply does not materially affect the amount of protein in the plants, though with low nitrogen supply there is a marked reduction in the amount and proportion of non-protein nitrogen and, in particular, a much lower proportion of amide nitrogen. These effects are not, however, observable in the seeds, where low nitrogen supply reduces the total nitrogen present, but does not cause any significant variations in the proportions of protein and non-protein nitrogen. The proteins of the seeds, on the other hand, possess lower proportions of amido nitrogen and higher proportions of mono-amino nitrogen when nitrogen supply is low. Finally, the low-nitrogen seeds contain a much smaller proportion of gluten than do those supplied with abundant nitrogen. In both sets of seeds, the physical properties of the glutens and the ratio of alcohol-soluble protein to alkali-soluble protein appear to be identical. The author concludes that differences in nitrogen nutrition do not produce any essential difference in the quality of the kernels except those due to varying amounts of gluten. The variations in quality of grain of any variety of wheat grown under field conditions are, therefore, due to other factors.

North Pennine Ore Deposits. The well-known mineral fields of Alston Moor and Upper Weardale have been studied in detail by Dr. K. C. Dunham (*Abs. Proc. Geol. Soc.*, p. 47, 1934). The mineralised area is divided by the faulted monocline of Burtreeford into two crudely circular areas within each of which the minerals are distributed laterally and vertically in well-marked concentric zones. Three zones of gangue minerals are recognised: a central fluorspar region (281 veins), a broad peripheral fringe of barytes, with local witherite (208 veins); and an inconstant transition belt (17 veins). From each centre the successive sulphide zones are characterised by (1) notable amounts of chalcopyrite, (2) galena with subordinate zinc blende, (3) galena and zinc blende in roughly equal amounts, and (4) galena alone, blende falling off rather abruptly. Sulphides die out beyond the galena zone and the veins become almost entirely barytic. The zonal arrangement is superimposed on the Carboniferous formations and the Whin Sill with complete impartiality. This marked independence of distribution serves to dismiss the old lateral secretion hypothesis, and to prove that the Whin Sill was not directly concerned with the mineralisation. It is suggested that the ores were introduced by hydrothermal solutions derived from certain deep-seated foci of intrusion (each corresponding to a dome of mineralisation), of which the representative igneous rocks have not yet been revealed.

Initial Motion of Earthquakes. Two years ago, Mr. T. Fukutomi noticed a similarity in the direction of the initial motion of earthquakes in certain parts of the Kwanto district, Japan. He has recently studied the distribution of earthquakes with similar initial directions of motion with fuller materials (*Bull. Earthq. Res. Inst.* 11, 510-528, 1933), using earthquakes with distinct initial vertical motion in Tokyo from 1914 until 1932 and originating within 100 miles of the city. The total number of such earthquakes is 337, in 176 of which the initial motion was upward and in 161 downward. The epicentres of earthquakes with the same initial direction are grouped in rather definite areas. Thus, the earthquakes originating beneath the basins of the Rivers Kinu and Ogai, the southern part of the Boso peninsula, in the Idu peninsula, etc., begin with an upward movement at Tokyo; those in the Kasugaura, along the shores of Tokyo Bay, and in the central part of the Boso peninsula, with a downward movement. The writer concludes that the earthquakes originating in the two main regions are due respectively to similar modes of origin.

Tuning Fork as a Standard of Frequency. A paper by the late Dr. Dye and L. Essen has recently been published on the valve-maintained tuning fork as a primary standard of frequency (*Proc. Roy. Soc.*, A, Feb.). The fork used has a massive base and prongs cut from a bar of elinvar and has been in use since 1922. The effect of changing a number of variable factors on the period of the fork has been investigated. The period is independent of the exact way in which the base is clamped only if the prongs are accurately balanced, and a method for doing this is described. The variation with polarising magnetic field, with amplitude, atmospheric pressure, and with the voltages and loadings applied to the driving circuit were all studied and a design for the fork equipment evolved. The residual instability of this arrangement was mainly due to small changes in the voltages applied to the valve circuits and to changes in pressure within the fork enclosure. With improvement in the conditions, the fork is expected to show a long period constancy of one part in 10^7 and a short period constancy of a few parts in 10^9. It is stated that a small reaction occurs between the fork and another oscillator used for comparison; this might be avoided by the appropriate use of screen-grid valves.

Polarographic Researches. The phenomena associated with the deposition of metals at the dropping mercury cathode have been the subject of investigations during the last few years by Prof. J. Heyrovský and his co-workers. Recently the method has been extended to micro analysis. Thus, it has been successfully adapted to the estimation of iodine in Chile saltpetre, the analysis of petroleum distillates for reducing agents and in the electro-reduction of many organic compounds. The way in which the platinum elements lower hydrogen overvoltage has also been demonstrated by the polarographic method. A further illustration of its diverse applications is afforded by its use in biological investigations on the adsorption factor of serum and on the lymph in cutaneous diseases, in which the dermatologist, Dr. Petráček, made good use of the method. Perhaps the most striking results obtained with the polarograph are those of Dr. Brdička, who has studied the catalytic action of cobalt ions upon protein decomposition. It is found that the protein content of a fraction of a milligram of material can be estimated by this means. The amount of cysteine in a millimetre of hair has been determined and, apart from its analytical value, Brdička's work has an important bearing upon the elucidation of the co-ordinating properties of polypeptides and their decomposition products. For Czech readers, Prof. Heyrovský has just compiled a monograph summarising the applications of the polarographic method in practical chemistry under the title, "Použití Polarografické Methody v Practické Chemii" (Pp. 132. Published by the Czechoslovak Society for Research and Testing of Materials, Prague III). The monograph, which deserves to be translated into English, gives a comprehensive account of the researches carried out with the polarograph. The bibliography contains 139 references.

Social and Industrial Development of Rural Communities

THE twenty-third report of the Development Commissioners[*] for the year ended March 31, 1933, is much more than a mere collection of official statements of the various activities directed by the Commission. The report no longer sets forth the work in progress at research institutes and advisory centres in Great Britain, as this will be dealt with in the publications of the Agricultural Research Council and the departments of agriculture. Brief accounts of the institutes are given, touching on their *raison d'être*, personnel and finances, but the chief emphasis is laid on the progress of various schemes which the general public scarcely realises as coming within the scope of the work of the Commission.

In most rural districts in Great Britain, very slow progress has been made by electrical supply schemes, as the cost has been beyond the reach of most rural dwellers, largely because of the distance that current has to be conducted as compared with urban areas. Special arrangements were made to supply a rural area in Bedfordshire with electricity under special terms, and considerable progress has been made during the three years of the scheme. The majority of rural customers use electricity for domestic purposes only, but its use in farm buildings and dairies is gradually spreading, and about 62 per cent of all the premises within the area are now receiving supplies. The most important factor responsible for the progress made seems to be the adoption of a lower tariff than in most rural areas, together with special facilities offered by the Bedfordshire Corporation for assisted wiring without consumption guarantee. It is anticipated that by the end of 1934 revenue from this source will exceed expenditure and yield surpluses from which the advance from the Development Fund will be repaid.

For the last twelve years, the Rural Industries Bureau has been working largely for the benefit of local craftsmen, in association with the National Council of Social Service, the Rural Community Councils and Women's Institutes. Progress was at first slow, partly because of the difficulty of establishing contact with isolated village craftsmen, and partly because such craftsmen viewed the activities of the Bureau with suspicion and failed to realise that it had any value in putting them into touch with the work they needed so badly. Now that confidence has been established, about two thousand craftsmen are in touch with the Bureau's officers, but it is probable that at least three times as many have not yet been reached. The activities of the Bureau are multifarious; craftsmen are trained to make such things as fine ironwork, good furniture and substantial fruit baskets; local textile industries are reviewed and their products adapted to present-day requirements; exhibitions are staged at county shows and local fairs, and every endeavour is made to bring the craftsman into touch with a market for his productions. In general, both the purpose and policy of the Bureau may be summed up in the words, the "Craftsman's Friend".

For some years the Society of Friends has given special attention to allotment cultivation as a means of alleviating distress. In 1930, Government granted £80,000 to the Ministry of Agriculture towards aiding the provision of allotments for the unemployed, but after the financial crisis in 1931 this grant was not continued. However, the Society of Friends decided to carry on the work itself and to obtain money by public subscription. Its efforts were so successful that the 1933 programme catered for providing 100,000 persons with allotments, and Government assistance was applied for. The application was referred to the Development Commissioners, who recommended a grant of £10,000 on the £1 for £1 basis, and a further sum not exceeding £2,500 on the basis of £1 for each £2 raised by the Society of Friends. Certain conditions were laid down as to the application of the grant, which included Scotland in its scope. In actual practice, the cost of carrying out the scheme for the cropping year 1933 worked out substantially below the estimate, chiefly owing to the low price of seed potatoes.

On the fisheries and harbours side, much progress has been made in the extension and improvement of the breeding of shellfish. A simple and effective method has been evolved of rendering mussels and oysters contaminated by sewage clean and safe for human consumption, by placing them in tanks of sea-water made sterile by the addition of minute quantities of chlorine, which is afterwards removed so as to allow the shellfish to function freely. The investigations on the furunculosis disease of salmon, sea trout and fresh water fish have advanced considerably, but show that there are formidable difficulties in preventing the spread of the disease.

The diverse instances touched on above indicate the wide range of social problems dealt with by the Development Commissioners and demonstrate very clearly the value of their activities in connexion with many and varied aspects of national life.

Recent Researches on Fuel Technology

ANYONE casting his mind back for twenty years cannot fail to remark on the greatly increased interest in the problems of manufacture and utilisation of fuels. This is largely, although not entirely, a legacy of the War and its interruption of normal supplies, the rise of economic nationalism and the lesson of what could be achieved by the purposeful application of science. Early efforts were individual, in private concerns or educational institutions, but all over the world, State action has followed; for example, the British Fuel Research Board was established to study the production of liquid fuel for the Navy by the carbonisation of coal at low temperatures. Experience soon showed that no immediate solution lay in that direction, and the Report of the Board for the year ending March 31, 1933 (H.M. Stationery Office, 2*s*. 6*d*. net) shows that this aim is still unattained, although retorts of new design are giving promising service.

A limited quantity of oil and spirit from low-temperature tar has been supplied commercially to

Government departments during the last year. Experience has shown that low-temperature tars are particularly susceptible to a hydrogenation-cracking and some can be converted into motor spirit with a yield of nearly 100 per cent by volume, the tar acids being eliminated. Private concerns have accumulated much experience with the hydrogenation of coal and oils but their experience is not available. This adds to the interest of the Board's experiments on the mechanism of hydrogenation.

It has been shown that minute quantities of certain catalysts, for example, 0·067 per cent of some tin compounds, are effective. This emphasises the importance of the inorganic constituents of coal, and coal ashes are being examined spectroscopically to find whether coals exist containing germanium. Such observations stress the importance of the Physical and Chemical Survey of National Coal Resources, perhaps the most important branch of the Board's work, which now covers all the British coalfields. The rôle of the State in the prosecution of fuel research has its critics, but it must be allowed that private enterprise has failed to accumulate and provide the consumer with reliable information about the properties of its wares. Indeed it is a remarkable fact that the Survey has been established against the hostility of less enlightened coal-owners. Another notable item in the report is the publication of a collection of 365 analyses of commercial grades of coal raised in the South Yorkshire area. Actually this is a most useful publication, but in most industries, private concerns bear the cost of supplying the tests of their own commercial products.

The systematic survey not merely shows what is available underground but also suggests at times how the product can be improved by modifying the methods of working the coal. The Survey has confirmed the assertion that British coal seams are among the finest in the world and that with attention to the preparation for the market the product can meet any competition for quality.

Domestic fuel forms a big item in the national fuel bill, and work of general interest is reported. Many consumers can try for themselves the suggestion of making packets lined with aluminium foil containing coal slack. These, when placed on an open fire, hold together long enough to allow the coal to coke and then burn as a lump fuel.

These are a few items from the many investigations mentioned in the report, which covers practically the whole field of fuel technology. Certain investigations in university and other laboratories are also being supported financially, but on a reduced scale as a measure of national economy. H. J. H.

Cosmic Rays

KOLHÖRSTER has recently published a critical discussion of the nature of the cosmic rays (*Phys. Z.*, Nov. 15). He points out that the cosmic rays may be investigated by the use of the ionisation chamber, the Geiger counter or the cloud chamber. The distribution of the ionisation in latitude shows variations which indicate that some at least of the rays are particles which can be deflected by the earth's magnetic field. A small azimuthal asymmetry has been detected which may indicate that an excess of the incident particles are positively charged.

Magnetic deflection experiments have not led to unambiguous results. The rays appear to be very fairly constant in intensity, though periodic variations of the order 2 per thousand may possibly occur during the sidereal or the solar day. The variation with barometer, due to absorption in the atmosphere, is well marked, and tends to obscure lesser variations. From time to time large bursts of ionisation are observed (*Stösse*) which are presumably of secondary origin. The curve connecting ionisation with height in the atmosphere has been repeatedly obtained up to the tropopause and some data exist at higher altitudes. The absorption of the radiation in water has been investigated. When the rays pass into a heavy absorbing medium, there is an anomalous variation in the absorption coefficient which indicates the production of a secondary radiation, and the production of such radiation is indicated by experiments with multiple coincidences of Geiger counters. The author concludes that the primary radiation is probably of corpuscular type. There is a long and useful, though incomplete, collection of references to the literature.

In the same number of the *Physikalische Zeitschrift*, Regener describes new measurements of cosmic rays in the stratosphere using his beautiful self-registering electroscope, while the *Journal of the Franklin Institute* of December 1933 contains an account of the photography of the *Stösse* by a Wilson chamber method. G. L. Locher arranges the Wilson chamber so that it is fired automatically by the discharge of three non-collinear counter-tubes. The showers observed often appear to originate at two or more points and must apparently be initiated by non-ionising secondary radiation, since their origins are frequently not collinear. There are also short tracks which are similar to those produced by recoil atoms from neutrons.

Index of Business Activity

IN a paper read before the Royal Statistical Society on January 16, Mr. Geoffrey Crowther described the "Index of Business Activity" which has recently been prepared by the *Economist*. Mr. Crowther pointed out that, up to the present, it has not been possible to measure statistically the amplitude of fluctuations in the general activity of the community. Indices of production are familiar in most countries and in the absence of a more suitable index, they are frequently used as indications of business activity, though they have obvious weaknesses for this purpose.

Productive industry is still the foundation for all economic wealth, but the superstructure of distribution and service is yearly growing in size and importance. Moreover, it is a well-known economic phenomenon that the swings in activity in productive industry are considerably greater than the fluctuations of the economic life of the community as a whole.

An index of business activity must therefore cast its net far wider than industrial production. It must take account not only of the rate at which goods are produced but also of the rates at which they are distributed, transported and sold

The *Economist* Index of Business Activity
(Average for Year)

1920	97·8	1927	107·8
1921	74·5	1928	105·9
1922	88·8	1929	110·0
1923	94·4	1930	105·9
1924	100·0	1931	96·3
1925	101·8	1932	95·8
1926	93·6	1933*	99·5

* Provisional, 11 months average

The *Economist* "Index of Business Activity" is published monthly and is based on a weighted series of indices relating to employment, the iron and steel and cotton industries, imports of raw materials and non-ferrous metals, exports of manufactures, railway traffic, shipping movements, consumption of coal and electricity, postal receipts, bank clearings, building activity and the registration of motor vehicles

History of Mathematical Time

TWO articles under the above title by G Windred have been published in *Isis*, 19 and 20, in 1933 In the first the author traces the development of the concept of mathematical time from its origins with Napier, Barrow and Leibniz up to the theory of pure time of Sir William Rowan Hamilton. Within the short space of some thirty pages, the author gives an excellent account of Barrow's theory of mathematical time, which formed the basis of the time concept in Newtonian mechanics for more than two centuries. He traces the progress of the concept in the writings of Newton, Maclaurin and Kant, and concludes with a brief account of Hamilton's views on algebra as the science of pure time.

The second article is devoted to the history of time in the mathematical physics of the twentieth century. The author gives a brief account of the fundamental papers of H A. Lorentz, Poincaré, Einstein and Minkowski concerning 'local' time, simultaneity of events and the synthesis of space and time into one whole in the special theory of relativity. He passes on to a relatively full account of Robb's theory of 'conical order' and concludes with brief references to the later work of Einstein, the system of time due to A. N. Whitehead, the views of Eddington, Vasiliev and Synge, and recent ideas on the atomic structure of time, due principally to Robert Lévy and Pokrowski. Here one misses any reference to the writings of H. Reichenbach, more particularly his "Philosophie der Raum-Zeit-Lehre", 1928, where a good deal of space is devoted to a discussion of the nature of time. Apart from this omission this part of the essay gives a clear and relatively full account of the changes brought about by the advent of the theory of relativity in our ideas of time. The last section of the essay gives a summary of the applications of the theory of time to mechanics and mathematical physics and of its implications for philosophy and psychology.

The essay can be highly recommended to anyone, whether mathematician, philosopher or physicist, who needs a brief summary of the history of the concept of time from its origin to its latest developments. It is well supplied with references and so can serve as a guide to anyone desirous of studying the question more completely than is possible in so short an essay.

University and Educational Intelligence

CAMBRIDGE.—The Buildings Syndicate recommends that the vacant site between the Museum of Archæology and Ethnology and the Botany School be assigned for an extension of the Museum, provided that this assignment be reconsidered if no permanent building is erected on the site within ten years.

The Council of the Senate recommends that a pension of £430 a year be granted to Prof J. T. Wilson on his retirement from the professorship of anatomy

The Faculty Board of Medicine recommends the establishment of a Marmaduke Shield scholarship in human anatomy of the value of £100 a year.

OXFORD.—In Congregation on March 3, the degree of D Sc was conferred on Charles K Meek (Brasenose College), Government anthropologist in Nigeria, and author of three important works: "A Sudanese Kingdom" (1931), "Tribal Studies in Northern Nigeria" (1931), "The Northern Tribes of Nigeria" (1925)

ADULT education is being exploited in the United States on a vast scale by the Federal Emergency Relief Administration as a means of providing work for unemployed teachers (including many unemployed persons who are potential though not professed teachers) and at the same time raising the standard of employability of the general mass of unemployed Any person now on relief or urgently in need of a job, who is a college graduate or able to offer other proof of intellectual ability, is to be given an opportunity of employment as teacher. The scheme has six divisions, of which two are outside the field of adult education: teaching of 'illiterates', which is construed to mean education of adults up to sixth-grade level, general adult education, trade schools, training of physically disabled persons, reopening of rural schools closed for want of funds to pay teachers, and nursery schools in mining camps, mill villages and other places where children, especially children of the unemployed, are not being adequately cared for. It is anticipated that where the local organisation is slow in developing a general adult educational project, a competent unemployed scientific worker will work up a class for himself to teach, whereupon he will be enrolled as a paid instructor. The rates of payment have been revised, the former limit of 15 dollars a week having been withdrawn The trade schools will provide employment for many engineers thrown out of work by industrial depression and the nursery schools will absorb some of the unemployed women trained in child psychology or kindergarten. *School and Society* of December 2 has an authoritative leading article describing the scheme.

Science News a Century Ago

Darwin in the Falkland Islands

Between March 10 and April 7, 1834, H M S. *Beagle*, for the second time, was in the Falkland Islands, and on March 16–19 Darwin made an excursion inland with six horses and two Gauchos, "dexterous hands in all the requisites of making the camp life comfortable", who to Darwin's surprise made a fire, nearly as hot as a fire of coals, with the bones of a bullock lately killed but from which all the flesh had been stripped by vultures Describing the Islands in his "Journal of Researches", the archipelago, he said, "is situated in nearly the same latitude with the mouth of the Strait of Magellan , it covers a space of one hundred and twenty by sixty geographical miles, and is little more than half the size of Ireland After the possession of these miserable islands had been contested by France, Spain and England, they were left uninhabited The Government of Buenos Ayres then sold them to a private individual, but likewise used them, as old Spain had done before, for a penal settlement England claimed her right, and seized them The Englishman who was left in charge of the flag was subsequently murdered A British officer was next sent, unsupported by any power · and when we arrived, we found him in charge of a population, of which rather more than half were runaway rebels and murderers."

"The theatre is worthy of the scenes acted on it An undulating land, with a desolate and dreary aspect, is everywhere covered by a peaty soil and wiry grass, of one monotonous brown colour Here and there a peak or ridge of grey quartz rock breaks through the smooth surface Everyone has heard of the climate of these regions ; it may be compared to that which is experienced at the height of between one and two thousand feet on the mountains of North Wales ; having however less sunshine and less frost, but more wind and rain "

The Fullerian Professorship of Physiology

In 1833 John Fuller, a wealthy and somewhat eccentric member of Parliament and landowner of Rose Hill, near Robertsbridge in Sussex, endowed at the Royal Institution the Fullerian professorship of chemistry which was held by Faraday to the end of his life. Fuller, if the tales about him are to be believed, was distinguished alike for his turbulence in the House of Commons and his somnolence in the lecture theatre of the Royal Institution, but he had an abiding respect for the Institution and the philosophical attainments of its professors. Early in 1834 he expressed to the Managers his wish and intention of founding another professorship. His offer was gratefully accepted, and on March 10, 1834, he executed a deed of endowment creating the Fullerian professorship of physiology. Unlike the chair of chemistry, which in a hundred years has been occupied by only five professors, Faraday, Odling, Gladstone, Dewar and Bragg, that of physiology was to be tenable for a limited period of three years. The first professor was Peter Mark Roget, physician, and secretary of the Royal Society. Roget was the author of that invaluable book of reference, the "Thesaurus of English Words and Phrases", a work which in recent years has extended his fame to the wide and unthought-of circle of those who take their crossword puzzles seriously.

John Fuller, in founding his professorships, added to the benevolent purpose of making some return to society for the benefits he had received during a long life, the patriotic intention of helping to maintain Britain's great and growing reputation in the field of scientific inquiry. His professors have fulfilled his intention. The list of the Fullerian professors of physiology is a much longer one, but it is no less distinguished than that of the professors of chemistry, and includes such names as Huxley, Owen, Michael Foster, Ray Lankester and Sherrington. Only twice in its history has the chair been held for a second period of three years, by Thomas Henry Huxley and, more recently, by Sir Arthur Keith

Great Western Railway

The Great Western Railway may be said to have had its birth at a public meeting held in Bristol on July 30, 1833 Eight months later, on March 10, 1834, in the House of Commons, petitions for and against the line were presented, and the second reading of the bill for the railway was passed by 182 votes to 92. The petitions in support of the line came mainly from the towns such as Bristol, Bath, Stroud and Cheltenham, while those against the line were mainly from the landowners in Berks and Bucks and "certain individuals residing at Earl's Court, Brompton" The Marquis of Chandos, in opposing the bill, said he did so principally on account of the strong feeling that existed among the landed interest of that part of the country he had the honour to represent Not only would the line pass through many private grounds and subject the occupiers to all the inconveniences attending it, but in many cases it would entirely destroy valuable farms and other private property, from the deluge that would be occasioned in the lowlands by the embankments that must be necessarily thrown up on each side of the line Capt Dundas objected to the railway as "it would turn adrift many hundred seamen in the coasting trade , and if the bill was carried, the next railway would be to Shields and Sunderland to carry coals, and then the navy would be ruined, and the breed of seamen soon become extinct"

Foundation of the Statistical Society

"A new Society under this title has arisen from last year's meeting [1833] of the British Association for the Advancement of Science The eminent individuals who formed the committee of the Statistical Section at Cambridge invited a public meeting at the rooms of the Horticultural Society on the 15th of March [1834]. There were about 250 persons present, and the Marquis of Lansdowne took the chair His lordship informed the meeting that the Government would be glad to avail itself of the labours of such institution , which, in return, should have the assistance of Government when it was necessary The Lord Advocate, Mr. Babbage, Mr. Jones, of the London University, Mr. Spring Rice, Mr. Hallam, and Mr. Brunel spoke warmly in favour of the projected institution. The following resolutions were passed unanimously— That accurate knowledge of the actual condition and prospects of Society is an object of great national importance, not to be attained without a careful collection and classification of statistical facts—That a Society be established by the name of the Statistical Society of London ;

and that the Society consist in the first instance of such of the present company as shall subscribe an obligation to that effect—That the Committee be empowered, until the day of the next meeting, to receive the signatures of additional members, and to admit them Fellows of the Society Messrs Babbage, Jones, Hallam, and Drinkwater were nominated a Committee M Quetelet, of Brussels, to whom the formation of this statistical section of the British Association at Cambridge was mainly due, was elected the first honorary member.

"A statistical society was founded three or four years ago in Paris, and similar societies are now forming in other countries This disposition of mankind to associate together for common objects will lead, at no distant period (viz, at the time when representative governments shall have become general), to European, American, and Cosmopolitan Societies, composed of members of all the governments of Europe, America, or the world meeting together to devise plans for the good of all mankind Among these will be, universal education, a universal system of weights, measures, and moneys, one common language, one common law, and universal freedom of commerce As to the question of peace or war, there will be very little danger of the latter, when it is not the interest of any particular class of men to make it" (*Gentleman's Magazine*)

Societies and Academies

LONDON

Royal Society, March 1 A J Bradley and J. W Rodgers The crystal structure of the Heusler alloys In an investigation of the ferromagnetic alloys of copper, manganese and aluminium, an alloy was found which showed an almost complete change of crystal structure due to heat treatment Drillings of this alloy, which had been annealed at 500° for several hours and cooled slowly to room temperature, were found to have the δ copper aluminium (Cu_9Al_4) type of structure The alloy is non-magnetic, but on quenching from 800° C it becomes strongly ferromagnetic The structure is now entirely body-centred cubic, with a face centred superlattice On comparing X-ray powder photographs of the same specimen made with radiations from iron, copper and zinc anticathodes, it was found that the relative intensities of the weaker reflections varied with the wave-length of the radiation This made it possible to distinguish the manganese atoms from the copper atoms C Sykes and H Evans Some peculiarities in the physical properties of iron aluminium alloys An account is given of measurements of the resistivity of alloys of iron and aluminium containing 11–16 per cent aluminium by weight Resistivity at room temperature depends on the rate of cooling of the specimens from a temperature of the order of 600° C. Alloys in this range consist of a single solid solution at all temperatures concerned It is concluded, therefore, that rearrangement of atoms takes place in the alloys under slow cooling conditions, and the more regular arrangement so produced leads to a decrease in resistance Experimental results suggest that the rearrangement of atoms in the space-lattice takes place over a considerable range of temperatures even under conditions of very slow cooling.

DUBLIN

Royal Dublin Society, December 19. J Reilly, P. P. O'Donovan and Miss H. Murphy · A note on the molecular complexity of amylose in potato starch. Cryoscopic determinations of the molecular weight of dry amylose dissolved in acetamide gave consistent values corresponding to the formula $(C_6H_{10}O_5)_2$. Desiccation experiments showed that drying at 78° C. under 10 mm pressure completely removed all water and alcohol from the amylose, so that the relative simplicity of the molecules in acetamide solution could not be attributed to the formation of polysaccharide water or alcohol complexes On the other hand, the ash-content of the amylose could not be reduced much below 0 9 per cent, and it is suggested that the presence of this small quantity of ash may possibly be of importance in the depolymerisation of the amylose. Joseph Doyle and Mary O'Leary Abnormal cones of *Fitzroya* and their bearing on the nature of the conifer strobilus The structure of abnormal staminate and hermaphrodite cones of *Fitzroya* is described. On the basis of these structures it is tentatively suggested that —(*a*) the stamen and the bract of the ovulate cone are homologous. (*b*) There is no auxiliary structure, particularly no reduced branch, in the organisation of the ovulate cone, the ovules being directly related to the bract (*c*) Neither bract nor stamen is a sporophyll in the sense of a structure in any way similar to a vegetative leaf carrying sporangia (*d*) Both bract and stamen are the end development of an extreme reduction of a primitive *reproductive branching system carrying sporangia*, probably terminally, on the ramifications, the main plan of the cone being attained before, or at least independently of, the photosynthetic development *which gave rise to the leaf.*

PARIS

Academy of Sciences, January 15 (*C R*, 198, 213–292) The president announced the death of Paul Villard, member of the Section of Physics, Paul Vieille, member of the Section of Mechanics and Jean Cantacuzène, *Correspondant* for the Section of Medicine and Surgery Hadamard Observation on a recent note by M Adamoff E Jouguet Indifferent points and critical points Ch Achard and Léon Binet The effects of sodium thiosulphate on poisoning by potassium cyanide From experiments with fish it has been shown that sodium thiosulphate exerts a curative action in poisoning by potassium cyanide J Favard A surface with given boundary Paul Alexandroff The local properties of closed ensembles Mandelbrojt · Fourier's series with gaps. F Leja A method of construction of Green's function belonging to any plane domain. A. Rauch. ROME

Royal National Academy of the Lincei: Communications received during the vacation. E. Almansi: Deformations of elastic strips (9). In this final note, various further questions of purely analytical character are considered. T. Viola: Baire's functions of the first and second classes. If $y=f(x)$ and $x=\varphi(t)$ are two functions of Baire's first class, the compound function $y=F(t)=f(\varphi(t))$ is, at the most, of the second class. The conditions under which it can be affirmed that this compound function is of the first class are now discussed. A. Terracini: Congruences associated with respect to a surface. C. Bertolini: Study of an equation to the partial derivatives of the third order. R. Caccioppoli: Non-linear elliptic equations to partial derivatives. B. de Finetti: Classes of equivalent aleatory numbers. Maria Cibrario: Bernoulli's and Euler's numbers. C. Agostinelli: Geodetic curvature of dynamic trajectories. Z. Pycha: Radius for waves associated with phenomena. V. Kupradze: Diffraction of elastic waves on an elliptic contour. G. Racah: Number of isotropic and hemi-isotropic tensors in spaces of several dimensions. The results previously obtained in determining the number of isotropic tensors of a Euclidean S_3 are extended to Euclidean spaces of several dimensions, true isotropic tensors being separated from hemi-isotropic tensors. D. Palermo: Surface dilatations of elastic solids. G. B. Bonino and G. Centola: Investigations on the theory of concentrated solutions of strong electrolytes; possibility of extension to the calculation of osmotic coefficients. The theoretical considerations used previously for calculating the activity coefficients of strong electrolytes are now applied to calculation of the osmotic coefficients of such solutions. Good agreement with experimental data is shown. F. Garelli and G. Racciu: Ethylacetanilide as a cryoscopic solvent, and the molecular weights of certain cellulose esters dissolved therein. This solvent crystallises better than triphenyl phosphate and freezing points of its solutions are easier to read. For its molecular freezing point depression the mean experimental value is 85·8 and the calculated value 87. At low concentrations, nitro-, acetyl- and ethylcelluloses form true solutions in ethylacetanilide, their molecular weights corresponding with the dimeric formulæ $(C_6 \times 2)$. A. Rossi and A. Iandelli: Crystalline structure of the compound MgPr. This compound forms monometric crystals of density 4·67. The unit cell, of side 3·88 A., contains one molecule. G. Mezzadroli and A. Amati: Action of certain alkaloids on the metabolism of glucides by *Aspergillus niger*. The consumption of glucose or sucrose by this mould in Wehmer's or Raulin's solution is increased by the presence of 0·05–0·3 per cent of strychnine or quinine, but caffeine has the opposite effect. R. Novello: Observations on the activity of chloroplasts in a southern climate. Of 114 plants studied, 91 showed amyliferous chloroplasts, lipids also being present in 55 cases. Chloroplasts with only lipid inclusions were found in 19 plants, whilst with 4 of the plants neither starch nor lipids occurred in the chloroplasts. Lipids included in the cytoplasm were observed in a number of instances. R. Savelli: Heleochloroplasts. This name is given to a peculiar form of assimilatory plastid, characterised mainly by carrying a large parastromatic vesicle, and found in various plants. S. Genussa: Integration by quadrature of the equation $\partial^2 z/\partial x^2 - a\,\partial^2 z/\partial y^2 = f(x, y)$.

SYDNEY

Royal Society of New South Wales, November 1. E. C. Andrews: Origin of modern mountain ranges. Modern mountain systems comprise cordillera and ordinary plateaux. Both are earth undulations—broad and swelling as plateaux in the more stable earth structures, but crowded together to form cordillera in relatively unstable earth zones, with resultant subparallelism and syntaxis of ranges (with appropriate development of intermontane valleys). They are arranged marginally, in the main, to continents or great continental nuclei; their growth has been saltatory (punctuated with pauses of still-stand), yet so slow that large streams have maintained their ancient courses against the uplift; earth movements have determined the formation of the ranges, while isostasy, through rock flowage, has determined their form, namely, as undulations balancing each other in positions of variable unstable equilibrium. Earthquakes and volcanoes are incidental features. The cordillera and the main continental plateaux are physiographic unities, all being dependent upon a deep underlying and world-wide control operating in late and post-Tertiary time. A R. Penfold and F. R. Morrison: The essential oils of *Eucalyptus micrantha*, including a form rich in piperitone The essential oil of *Eucalyptus micrantha* (type) is of no economic value, but that obtained from the new variety, var. *A*, is of potential value since it contains 40–50 per cent piperitone M B Welch: Equilibrium moisture content of seasoned timber Whilst it was found that a number of timbers indoors in Sydney only showed a mean variation of about 2·0 per cent moisture, at Broken Hill and Hay the variation was nearly 8 0 per cent, and whilst individual timbers in country districts during summer contained less than 5 per cent, in winter the figure reached was nearly 19 0 per cent moisture Of a number of timbers used, Queensland maple showed the greatest fluctuation in moisture content

The Devolution of Government

POLITICAL events of the last year have scarcely encouraged scientific workers who are dubious about the capacity of our present structure of society to meet our economic, industrial or political needs without profound modification to look hopefully towards the corporate State as exemplified by Italy or Germany Not even Dr Levinstein's recent eulogy of nationalised industry is likely to tempt them to support policies so threatening to the stream of independent thought upon which progress in science, as in every other sphere, ultimately depends Nor is the alternative to Fascism as represented in Soviet Russia, for all the encouragement given to scientific research and to scientific methods, likely to turn them *en masse* to the support of the more extreme socialistic or communistic ideals

Scientific workers therefore who think less pessimistically than Mr G D H Cole, Prof H J Laski and others about the capacity of our existing system to modify and reform itself in accordance with the changed needs and demands, will be inclined therefore to give a sympathetic hearing to Capt Harold Macmillan's recent plea* for a national policy which is an alternative to either Fascism or Communism In his recent book he describes in greater detail suggestions previously made in his pamphlets "The State and Industry in 1932" and "The Next Step" which have already been noted in NATURE

The scientific worker should not be altogether unprepared for the proposals now outlined They have to some extent been foreshadowed by General Smuts in his lecture on "Science and Democracy", and represent essentially an attempt to find within our existing political constitution a means by which the expert advice and criticism may be brought effectively to play on the mechanism of Government It is an attempt to substitute knowledge for prejudice in the affairs of industry and State, without recourse to the autocracy which violent change either towards the left or the right is so liable to provoke, and displays an example of hard thinking which must be much more widely practised if we are to emerge from our difficulties and the recent slight improvement is not to prove a prelude to worst disasters

Capt. Macmillan unhesitatingly attributes the failure of the World Economic Conference to its failure to grapple with the underlying causes rather than with their effects. Agreement on tariffs, exchange restrictions, uneconomic prices, currency fluctuations, etc, could not be secured because of the deeper conflicts arising from economic nationalism and disproportion or disequilibrium in production. The problems of growth and change to which our social, political and economic organisation must be adjusted were not really faced, and solutions to them must be sought in a spirit of world co-operation as well as of world re-habilitation

---

* Reconstruction: a Plea for a National Policy By Harold Macmillan Pp xi+141 (London. Macmillan and Co, Ltd, 1933) 8s 6d net.

It is important to note the spirit in which Capt. Macmillan has conceived his proposals for reconstruction. As just indicated, in contrast to many other schemes, the policy he outlines seeks to improve our position without inflicting injury on our neighbours Too often economic policy is advocated or executed with an entire disregard of the injury it inflicts on other countries and the subsequent repercussions in our own trade This indeed is one of the strongest points in the plea for definite planning of industry, if only to ensure that action beneficial at first sight to one industry is not detrimental to industry or the nation as a whole or in the long run to that industry itself

The fundamental principle of planning should be beyond question at the present time The real issue is whether economic planning—the regulation of production in accordance with effective demand —is possible on a national scale as it is within definite limits with every successful individual producer, without incurring the dangers associated with such words as 'monopoly'. Capt Macmillan sees that, for adequate protection, regulative powers amounting to monopoly must be granted to efficiently organised and integrated national industries, but he is not intimidated by the word and considers that adequate safeguards are possible.

The essential principle of the plan advocated is the direction of production by a central authority for each industry through the grant of monopoly powers in return for the acceptance of certain social responsibilities. National industrial councils would be created for each industry or group of industries, the function of which would be to encourage and assist the efficient co-ordination of purchasing, production and research. Industry would thus become organised as a number of self-governing units enjoying sufficient authority to prevent a recalcitrant minority delaying progress or the continued erection of redundant plant by new producers where plant is already idle, of which conditions in the canning industry provide an unhappy example

Without some such self-governing authority it will continue to be difficult to prevent an industry from being robbed of the fruits of wise leadership, scientific management or co-operation through the disturbing influence of new producers Co-ordination of the policies of different industries would be secured through a Central Economic Council or Investment and Development Board, representing Government and finance as well as industry This Central Council, under the chairmanship of a Cabinet minister, would be a kind of industrial parliament, its duty being to advise the Imperial Parliament and carry out agreed industrial policies Since its function would be that of giving expert advice and the execution of Parliamentary decisions, there is no danger in the Central Council becoming a rival to Parliamentary government, indeed, owing to the Council's knowledge of the facts Parliament should be able to devolve on the Council tasks and functions which it could not itself perform

It is a bold claim that such a scheme, headed by a Central Economic Council on which trade unions are also represented, would provide a counterpart in the economic sphere to the political extension of the franchise It is not, however, lightly to be dismissed The scheme is a courageous attempt to relate more effectively knowledge and action, the hiatus between which has been responsible for so many of our ills Everything turns on the way in which the new powers conferred by the scheme are used. If they are used to determine action in accordance with the full facts, and not in accordance with half the facts or supposed facts, the machinery might well be worth a trial

The stress laid on social responsibility is accordingly vital The scheme must be worked in the spirit in which it has been conceived, and it is just the anti-social and incredibly narrow attitude of certain employers' associations to the unemployment question, and to proposals to alleviate that situation, which creates the most serious misgivings about the scheme. A like attitude, a similar refusal to recognise inconvenient facts and selfish disregard of the other side would wreck the whole scheme within a few months of its being launched. Given, however, a generous spirit, a wide vision of service and minds which set themselves unhesitatingly on the full facts, it might give us all that Capt. Macmillan claims. In any event it challenges scientific workers in all their contact with industry to promote such a spirit and atmosphere in which alone true reconstruction is possible. From their ranks must be drawn some at least of the leaders whose temper and knowledge can best serve the present occasions Already it seems almost certain that the solution of our problems depends on the evolution of new machinery of government, in which the individual and collective conceptions of society each find a harmonious place as well as permit the right relation of knowledge and power The violence which both conceptions alone have done to liberty and thought in recent years do not inspire confidence in their ability to lead mankind to higher levels, and science at least might be disposed to search for the truth in some such compromise as that conceived by Capt Macmillan

---

University Progress

History of the University of Edinburgh, 1883-1933 Edited on behalf of the History Committee by Dr A Logan Turner Pp xxxi + 452 + 26 plates (Edinburgh and London Oliver and Boyd, 1933) 10s net

THIS volume gives the record of fifty years of work in an old university—the youngest, and yet in some respects the greatest, of the Scottish universities Its most intimate appeal must therefore be to the multitude of the teachers and alumni who have passed and repassed the great gateways during the seventh of the inter-jubilee periods. Yet in that period wide problems of university finance and procedure and progress have arisen and been solved, or have been launched on the way to solution Questions of interest, or even of gravity, regarding the wisdom or unwisdom of steps taken, push themselves into consideration ; and, with institutions as with individuals, it is the sign of the sum total which matters On the credit side at least the total is never fully known,

"But, all the world's coarse thumb
And finger failed to plumb,
So passed in making up the main account,
All instincts immature,
All purposes unsure,
That weighed not as the work, yet swelled the whole amount,"

were of positive value though they can have no visible place in this volume.

The University of Edinburgh differs from all the other Scottish universities in that it originated outside Church influence , it was 'The Toun's College' And right well, on the whole, did the city fathers guard and nourish its infancy and youth until, in the progress of the centuries—about the middle of the last jubilee period—it stepped forth on its own path Yet there was no complete severing of the old influence, as there could be no complete parting from the old home 'Town and Gown' still go hand in hand, and the voice of the city is heard in the councils of the University Through access to records, the present volume of the history extends, in a most interesting way, knowledge regarding the earliest stages of the development of the old College, beyond the information available fifty years ago when the first volume was issued.

Not in early days alone did poverty sit on the University benches—peer's son and ploughman's son together not then alone did city fathers struggle for the common good, while fathers and mothers in the cottages went stintedly so that the lad o' pairts might enter upon his life's struggle with the hall-mark of a university upon him Even to this day in Scotland (as elsewhere) there are university students who labour during long hours that they may learn in some of the rest These conditions have been eased largely during the fifty years by the generosity of benefactors—detailed in this volume—notably through the funds administered by the Carnegie Trust Yet this easement may be found to be not without its price There are many who think that the loss of the brave old spirit of independence would be too great a price to pay , and that is not least the thought of the dauntless few of the needful ones who will nevertheless accept no aid The funds of the Trust are in part supplied to students on the understanding that repayment in the future will be acceptable ; but conditions do not in general work out so in practice Another view is that the number of students who are thus encouraged to seek a university training unavoidably includes many who are not specially fitted to benefit thereby, and who would be more usefully trained in other ways At present the whole problem is made very complicated by the adverse world conditions

Another fear regarding trust-administered funds, when these are great, is that the trust tends to become a dictator This condition applies even to Government administration, although there is some safeguard in that case through Parliament In smaller matters also, donors who have become wealthy through their own efforts have a tendency to lay down restrictions having an import which lies beyond their own horizon Well back in the fifty years, Lord Rosebery warned the Scottish universities against the surrender of their autonomy. The compulsion of surrender is apt to arise insidiously, and perhaps even unpremeditatedly, so that all decisions regarding matters of national importance should be, even in their initiation, open to control All allocations of important funds should, with the reasons annexed, be open to scrutiny Yet it seems to be possible, at least theoretically, for a body such as the Carnegie Trust to come to decisions which might adversely affect individual universities A great example is given by the Treasury itself, which regards the universities as being themselves the best judges of the right mode of spending the grants of money which it makes to them The same wise course has been followed by several of the donors of munificent gifts which are recorded in this volume

The Scottish universities are tied together by the condition that a desired ordinance cannot be issued for one until it has passed the scrutiny of the rest Formerly the tie was more rigid and lay as a blight upon the possibility of individual advance A main purpose of the tie in its present form is to make impossible a step by one which might act detrimentally on the interests of another —a quite laudable object But a recent proposal that the University of Edinburgh should be empowered to grant an honours degree in pure science seems to have been opposed successfully by the University of Aberdeen on the grounds that the proposed degree was not of much higher standard than the present pass degree, that students who might not be capable of attaining a high standard of honours in the other honours science degrees would tend to compete for this relatively weaker degree, and that the proposal emanated from the schools Now it may not be impossible for the standard of the proposed degree to be higher than a low standard of honours in the present more special honours science degrees, and the institution of the new degree might quite conceivably make possible the abolishment of the present third class grade of honours in science, and so raise appreciably the standard of that more special degree. Near the beginning of the present jubilee period in Edinburgh, Chrystal grudgingly admitted the desirability of a third class grade in honours, and he did so in view of a need for an honours degree, for school teachers, which did not exact too high a standard of specialisation. If the schools recognise that the level of attainments of school teachers in general science should be greater than the level required for actual teaching, and if the proposal for such a degree came from the schools, so much the greater is the credit to them, and so much the greater is the likelihood of its wisdom But, at any rate for the time, Aberdeen has debarred the suggestion of Edinburgh

These are problems of a type which any university may have to face in its work for the nation, and there are other wider problems of policy of which the record in this volume gives examples One of the most important, which arose before the beginning of the half century and was solved in its early years, was that of the admission of women students In this matter the University of Edinburgh was a pioneer—the inevitable outcome of its pioneering work, in still earlier days, through the medium of extra mural classes for women, taught by members of the University staff Undoubted success has attended the step The number of students aiming at an arts degree has in consequence greatly increased, so that, in point of numbers, the Arts Faculty has now ousted the Medical Faculty from first place, and has become almost as much a Faculty for professional training The Divinity Faculty alone, although it has opened its classes to women students, has resisted the *Zeit-Geist* so far in debarring them from its profession The professional aspect of the problem accounts also for the great development of the young Faculty of Science within the fifty year period

Another interesting and successful development in these years is the partial return to the early residential condition obtaining in the Toun's College, through replacement of 'lodgings' by 'hostels' If it gives less complete conditions for study, it has other great advantages

The teaching staff has increased nearly sixfold in the fifty years, and the increase of departments and buildings has been on an explosive scale also—so much so that some critics doubt if it should not be regarded as a gamble rather than as an example of wise forethought But if, one hundred years ago, wisdom had foreseen the present compulsion to expansion, the huge sums recently expended on the acquirement of sites would have been immensely lessened and the scattering of university fragments over the face of the city would have been avoided But there was also want of prevision of the petrol motor which has made that scattering comparatively unimportant Since all knowledge is based upon faith, the exhibition of faith in the headquarters of knowledge is appropriate

Another, and one of the greatest, of the steps taken was the recognition of the body of students as a corporate part of the University, having a Representative Council established for the purpose of guarding the interests of the students, and empowered to express their views to the higher authorities The wisdom and influence of this step became at once apparent , and it was followed by the other Scottish universities, by English universities, and even by some on the Continent

Many other features of advance are recorded in the volume, and would repay study The social work of the University of Edinburgh Settlement, shared in by students, is notable , and especially so in its originative share in the general advancement of its work through extension to the work of the newly instituted Kirk o' Field College, where unemployed men receive, at their own request, education rather than entertainment, greatly though they appreciate the latter There, as the donor of the College building said, "The enthusiastic and generous minded student supporters of the Settlement had seen a great opportunity, a unique chance of turning apparent misfortune into co-operative effort, to further education, to revive the joy and pride of craftsmanship, and to weld the classes of the people in community of interest and ideal" , and, as the Chancellor said regarding these unemployed men, "How Scottish it was of them to do that, and how proud we ought all to be to remember that those men are Scottish ; they really are our brothers. They are going to get what they want—more lectures, more instruction All hail to them " They are worthy successors of the students of the earlier days

Though this volume contains records of deep interest to all who study the problems of education, general or scientific, it is in the hearts of many of the world-scattered army of nineteen thousand graduates that there will be raised by it vivid recollections of two powerful impressions made upon them in the days of their youth · one upon the day when first, with awed feeling, they passed beneath the lofty arches of the great gateway which seemed to them then to be the portal of the Temple of Destiny , the other on the day when the Alma Mater—Madam Edinburgh University, as the Chancellor called her—passed them out through the same gateway with the hall-mark of her approval upon them, and they knew it to be the gateway of the Temple of Life

"Never for her to reach the full meridian , and yet, see, watch how she makes around her an atmosphere of light Her eyes—her improbable eyes that you and I shall never fathom—they are fixed not on those 350 years, but on the next 350 that are now beginning She knows very well that the rack of the tough world must still be her portion But she is undismayed, stands full target for all the winds of the future She says 'For a University there can be no harbour' " So said Barrie, her Chancellor, and one of the great amongst her sons

Good wishes go with her as she "beats out to sea"

Mind and Brain

The Brain and its Mechanism By Sir Charles Sherrington The Rede Lecture delivered before the University of Cambridge, 5 December 1933 Pp 36 (Cambridge At the University Press, 1933) 1*s* 6*d* net

SIR CHARLES SHERRINGTON'S Rede lecture delivered at Cambridge last December, and now published, is an amazing compendium of conclusions covering the whole range of scientific inquiry in that field of Nature which has excited man's intensest curiosity

Primarily a manager of muscle, nerve and brain are but a skilfully laid train of powder between the muscles it fires and the restless world outside which fires it Some motor acts, essential but scarcely significant, as behaviour, are driven by nerve action generated within the brain itself The dominant partner in the driving of the brain is the outside world, wherein a limited set of agents working through nerve and brain can produce a thousand and one dexterous acts

The motor instrument is separable into a great number of small units usable individually and in many different combinations Each unit has a single nerve thread, which springs from a wide nerve net In the nerve nets occur at nodal points two kinds of nerve action, one which fires the nerve thread, the other which impedes or prevents this firing Conjointly, these two kinds of action neutralise each other quantitatively Given a large brain net, the animal's behaviour excels in variety and nicety, but is not radically different from the behaviour of reflex action.

Life's aim is an act not a thought, albeit to refrain is no less an act than other actions Inhibition is coequally with excitation a nervous activity One of the processes operative within the mechanism is a travelling signal, a brief local depolarisation of the electrically polarised surface layer of the nerve thread, involving a temporary electrical leak By repolarisation in the wake of the signal, the transmitting surface is repaired This activity involves work. The signals can be made to occur more frequently by intensification but cannot be made bigger In some parts of the brain the repolarisation process is rhythmic, and from such parts trains of signals start periodically

The nerve nets are patterned networks Junctional points provide that signals may converge and coalesce, reinforcing each other's power of excitation The opposite process, inhibition, does not travel but is evoked by travelling signals The nerve nets are, so to say, weighted with inhibition or with excitation This weighting leads to variation, even reversal of response

The brain initiates more than its fair share of acts and exerts censorship "A shell of its immediate future surrounds the animal's head" A vast expansion of the brain has arisen here where the signals from a distance combine Reflex action is enlarged and behaviour amplified The new membrane is so educable as to be practically a new thing in the world Each motor act becomes the servant of more masters, and an observer may judge that the reflex principle is departed from May it be that in those parts of the brain which may be called mental, nerve actions exist still unknown to us, and that these may correlate with mind? "There is, so far as I know, in the chemical, physical properties, or microscopical structure no hint of any *fundamental* difference between non-mental and mental regions of the brain" Nerve inhibition must be a large factor in the working of the mind, but the events we have to correlate with the mental events are not themselves of the reflex type they are back-watered signallings the circuits of which may long be self-maintained. Indeed we have no scientific right to conjoin mental experience with physiological events, but only the right of what "Keats with that Shakespearian gift of his, dubbed 'busy common sense'."

With the attainment of the objective of this exploration, Sir Charles Sherrington predicts that man will certainly try to improve the brain, "restraining some parts, amplifying others, introducing short-cuts, and certainly increasing speed and aiming at economy and devising as seems to him best We need not be prophets to foresee that then will come the long-told speedy extinction of man" This inference surely arises from data undisclosed?

Timbers of Commerce

A Manual of the Timbers of the World their Characteristics and Uses By Alexander L Howard Revised edition, to which is appended an Index of Vernacular Names Pp xxiii+672. (London Macmillan and Co, Ltd, 1934) 36*s* net

EVER since the publication of the first edition of this book in 1920, it has been widely used by timber importers and users of timber, and is looked upon as the standard work on the subject However, many kinds of timbers, some of which are now in use or in the experimental stage—particularly kinds of Empire origin—were omitted from the first edition, and Mr Howard has taken the opportunity of describing a large number of extra kinds in his new work An idea of the many additions may be gained from the two hundred or more pages that have been added to the present edition, all of which are devoted to descriptions. Moreover, the whole of the pages describing the artificial seasoning of timber in the earlier work have been used for timber descriptions in the new volume

Not all the timbers mentioned are used in the British Isles, nor are some of them likely to be used in the future, but they have come under the author's notice and he has included them in his descriptions In some instances timbers are only known to the author by their vernacular names; whether it was wise to include them without an effort to trace their botanical origin is very doubtful, but as Mr Howard is one of the leading timber importers in Great Britain, he doubtless has very good reasons for their inclusion, and with his very wide and varied knowledge of the uses and manufacture of timber, the correctness of the commercial side of the book should be beyond dispute.

An alphabetical arrangement of subjects is given, but it is open to criticism, for there is an indiscriminate mixing of common and botanical names which often results in some species of a genus being described with the common name most prominently placed, and in others the generic name being given the place of honour. The following examples are illustrations —

Alder,	*Alnus glutinosa*, Gaert.
Alder, Formosan	*Alnus maritima*, Nutt var *formosana*, Burkill [*A formosana*, Makino].
Alder, Red	*Alnus oregona*, Nutt
Alder, White	*Alnus rhombifolia*, Nutt

Five other subjects are then described and are followed by *Alnus nepalensis*, Don

On pages 145–146 three species of *Dalbergia* are described with the generic name first On pages 457–458 other species of *Dalbergia* are described under rosewood, and on page 487, *Dalbergia sissoo* is described under sissoo Many such examples occur There are certainly very good indexes to both common and botanical names, but in a work of this description, where botanical names are in constant use, it would have been a better arrangement and have given a much better impression had the author kept to a proper alphabetical arrangement of botanical names There are greater difficulties in following out a strict alphabetical arrangement of common names, for some timbers are equally well known in commerce under several epithets and many cross references would have been necessary

It is also regrettable that the author did not get someone well versed in botanical nomenclature to go through his manuscript, for there are numerous slips, one of which occurs on page 43 A timber is described as Avodire, and the botanical name is given as *Africana Bingeria* The name the author had in mind was really *Bingeria africana*, A Chev, which is actually a synonym of *Turræanthus africana* (Welw), Pellegrin

The misuse of capital letters in specific names is noticeable, and a good deal can be said for the decapitalisation of all specific names in books such as the one under review, a course that would certainly be less confusing for the author

Apart from these little defects the book has a great deal to commend it, for it is teeming with useful and interesting information, is well printed and well illustrated It should find a place amongst the most used books of timber merchants and manufacturers of timber W D

Short Reviews

Industrial Chemistry. By William Thornton Read Pp vii+576 (New York · John Wiley and Sons, Inc ; London · Chapman and Hall, Ltd, 1933) 31*s* net

THE four opening chapters of this volume deal with such matters as chemical organisations and literature, and the various functions of the chemist in industry. They might very well have been condensed considerably and, in parts at any rate, omitted, since they bring the author dangerously near that category of zealous exponents of the obvious which, according to his statement on p. 31, he desires to avoid. There is, however, much to be learned from the succeeding chapters on chemical economics, equipment and constructional material in spite of their pronounced American bias.

The remainder of the book is a series of brief but useful monographs on various applications of chemistry to industry, for example, the sulphuric acid, nitrogen, fertiliser, metallurgical, petroleum, electrochemical, rubber, coal, paint and explosives industries; foods, textiles and fermentation are omitted, although there are chapters on carbohydrates, proteins, oils and waxes

Since the author has wisely recognised that no one person can write with authority on the multifarious processes of chemical industry, he has enlisted the aid of ninety different authorities, and this help is amply justified by the excellence of the monographs. It has not, however, saved the book from certain omissions, such as of streamline filtration, submerged flame combustion and the use of esparto in paper-making, from a number of vague statements, for example, "white paper is made from approximately pure cellulose" and "tung oil is used in varnishes in connexion with pine resin which has been esterified with glycerin", and from a few serious errors such as in the definitions of the Reichert-Meissl and Polenske values of an oil

Apart from such blemishes, the book may be recommended as collateral reading for students of pure science and possibly also, as the author suggests, as a reference book for business men.

J. G

Ronay. a Description of the Islands of North Rona and Sula Sgeir, together with their Geography, Topography, History and Natural History, etc.; to which is appended a Short Account of the Seven Hunters, or Flannan Islands. By Malcolm Stewart Pp xi+73+17 plates. (London: Oxford University Press, 1933) 7*s*. 6*d*. net.

FEW people know of the existence of three uninhabited lands off the north-west coast of Scotland almost as isolated as St. Kilda These are North Rona, Sula Sgeir and the Flannan islands, seven in number with innumerable rocks. North Rona is a cliff-bound island rising up to 355 ft. and about 300 acres in extent; Sgeir is about 30 acres and 229 ft. high; and the Flannan 100 acres between them, with a height of 288 ft. on

Eilean Mor where there is a lighthouse All are formed of horneblende gneiss intersected by pegmatite veins and all probably came under the influence of the quaternary ice, for many fragments of alien rock have been found on each Sgeir has a gannetry with a population of 8,000 to the south of the island, its other birds consisting of as many razorbills and guillemots as well as puffins, kittiwakes, shags and fulmar; as on all such bird islands, vegetation is very scanty. The islands are visited every year from Lewis, Sgeir for young gannets and eggs, the others mainly for the fattening of a certain number of sheep transported from Lewis

Formerly, all would appear to have been inhabited, for they have the remains of unmortared stone houses These were half-sunk into the ground at Rona and were entered by crawling along passages Often large slabs of stone were used, and these would appear to have been turfed over, the only roof-opening being the smoke hole. There is also the remains of a chapel at Rona, now scheduled as a monument The author is not much interested, but the houses described as known to have been recently inhabited are very strikingly like the dolmen of Locmariaquer and Carnac and many other regions In conclusion, there is a short bibliography, but there is clearly a field here for the trained archæologist

Gas Analysis by Measurement of Thermal Conductivity By Dr. H A Daynes Pp viii+357 (Cambridge: At the University Press, 1933) 16*s* net

THE method is based on the discovery by Andrews in 1840 that changes in the composition of gas surrounding an electrically-heated wire are reflected in changes in the electrical resistance of the wire, and may therefore be measured on a suitably calibrated electrical instrument Thanks largely to the developmental work of Shakespear and the Cambridge Instrument Co in England, as well as to that of certain firms in Germany and the United States, it has now attained the status of a recognised industrial method, and as such is well worthy of a monograph to itself

The author is an authority on the subject, and his treatment of the theory, technique and applications of the method is all that could be desired The applications include flue- and fuel-gas control and measurements in connexion with the production of liquid air, gas permeability, for example, leakage through rubber and aircraft fabrics, nitrogen fixation, etc On account of the suitability of their thermal properties, carbon dioxide and hydrogen are frequently mentioned, and a number of useful indirect methods are described for the determination of other gases in terms of these

Possibilities of the method in academic research, for example, in physiology, are also indicated, and it is no exaggeration to state that there is something of interest here for every scientific worker, whatever his sphere and even if he is already using the method. J. G.

The Gyroscopic Stabilization of Land Vehicles By Dr. J F S. Ross Pp vii+172 (London: Edward Arnold and Co, 1933) 14*s* net

THIS book consists of a thesis approved for the degree of Ph D. in the University of London, and it gives the results of an investigation undertaken with the following objects "(i) To determine whether monorail traction is scientifically sound and definitely practicable, (ii) To show why the efforts of inventors have hitherto only met with partial success, and (iii) To place the whole subject on a more scientific footing and to give it a more complete and orderly treatment than it had yet received"

The text is, like most original papers, not easy to read, there are many places where the development would have been greatly enhanced by the insertion of explanatory paragraphs An excellent summary of the author's conclusions with references to the text is given at the end, together with a full bibliography and list of patents

The Flora of the Liverpool District Edited by C Theodore Green Pp xi+163+201 plates (Arbroath T Buncle and Co, 1933)

DR C T GREEN, the editor, thirty years ago, of the first edition of the "Liverpool Flora", is to be congratulated on the completion of this new and revised edition, also under his editorship

The general plan of this well-known flora remains unchanged Miss Wood's admirable line drawings, which express the 'look' of each plant in a most remarkable way, are still one of its most attractive features, though their reproduction is noticeably inferior in this edition. The chief innovation is the inclusion of five special articles on areas of particular interest, such as the Southport sand dunes, with notes on their topography and flora, illustrated by photographs. There are other small alterations, while, of course, a number of additional localities and records are given It is a volume which should be in the possession of all interested in this botanically rich area of Lancashire

Human Values in Psychological Medicine. By Dr C P. Blacker (Oxford Medical Publications) Pp viii+179 (London: Oxford University Press, 1933) 8*s* 6*d* net

THE author defines pivotal values as those which, in one way or another, unify and justify life, give it coherence and make it on the whole worth living. His conception of pivotal values is the really dominant idea of his book. After a number of chapters devoted to the discussion of values from a psychological point of view, the author studies the clinical aspects of the problem. He found that æsthetic values play a small part in the lives of working-class patients. He divides pivotal values into values which are neither religious nor philosophical. We are inclined to disagree with the statement that the majority of hospital patients have no "pivotal values". There are few people who have no pivotal values if only they can be touched on.

Hormones of the Anterior Lobe of the Pituitary Gland

IT is now generally admitted that the functions of the pituitary gland (or hypophysis) are mediated by the secretion of a number of hormones from its different parts, although no active principle has yet been isolated in the pure state, the fractionation of extracts has led to the preparation of solutions having only a part of the physiological activity of the original extract Differences of opinion exist as to the number of hormones actually present, which can only be settled when they are finally isolated as chemical individuals Our knowledge of the functions of the posterior lobe preceded that of the anterior, but within the last few years, with improvement in both chemical and surgical technique, and also following the discovery that hormones regulating certain of the sexual activities of the body are excreted in the urine, great advances have been made also in our knowledge of the functions of the anterior lobe

It appears probable that a number of different hormones are secreted by this lobe, but attention has been directed especially to those stimulating growth and the sexual glands One of the pioneers in this work has been H M Evans, of the University of California, the results of his researches, carried on over the last decade, are now available for study, in the form of a detailed monograph* Although the association of overfunction of the pituitary with body overgrowth (gigantism or acromegaly) and of its underfunction with dwarfism has been frequently confirmed, it was not until 1921 that Evans and Long succeeded in preparing an extract of ox anterior lobes which stimulated growth in mammals This was due to the facts that the growth hormone is a complex substance chemically resembling the proteins, is extraordinarily labile and can only be detected when administered frequently and parenterally to suitable animals Adult female rats more than five months old (which have therefore ceased to increase in weight), are injected intraperitoneally daily for a period of 20 days, groups of four to six animals are used and they are weighed every five days Gains in weight of 25–100 gm can be obtained according to the dose given, the relationship between the logarithm of the dose and the gain in weight was found to be approximately linear. E Biering and E Nielsen (*Biochem. J*, 26, 1015, 1932) have compared the composition of injected growing rats with that of normal growing rats and find that the former show a greater retention of water, but that the solid matter assimilated to the body tissues contains a much greater proportion of protein and less of ash and fat than that laid down by normal animals About three quarters of the gain in weight of the injected animals is due to water retention, and three quarters of the dry matter deposited consists of protein

The method of extraction recommended by Evans and his co-workers is briefly as follows frozen ox anterior lobes are minced and extracted with water made alkaline with baryta, the mixture is centrifuged and the solution brought to pH8 with sulphuric acid and again centrifuged The solution is then acidified and poured into excess of acetone, the precipitate is filtered off and dried. This powder is stable but still contains the gonad stimulating hormone On extraction with 95–98 per cent acetic acid, the latter is destroyed and the growth hormone can be precipitated from solution by acetone in the presence of quinine sulphate Trichloracetic acid precipitates the growth hormone and part of the gonad stimulating hormone from aqueous solutions of the powder, in the supernatant fluid the latter can be obtained free from the former by precipitation with flavianic acid, which is then removed by 80 per cent alcohol containing 1–2 per cent ammonia The purer growth hormone preparations are highly active in a daily dose of 5 mgm

Hypophysectomised rats show a greater response to the growth hormone regardless of age or length of time after removal of the gland Experiments with a hypophysectomised puppy are also described, the pituitary gland was removed when the animal was 8 weeks old, the operation was followed by complete cessation of growth Daily intraperitoneal injections of the growth hormone resulted in a marked increase in weight and size, so that the animal finally became larger than its litter mate control Signs of acromegaly, however, did not develop The ovarian follicles showed considerable development and the thyroid was hyperplastic Similar injections into a normal female resulted in the development of partial acromegaly, some gigantism and diabetes mellitus A male, however, only developed adiposity In dachshunds, the injections increased the size of the animals owing to increase in size of the skull and vertebræ, but the achondroplastic form of the short extremities was not altered, a male developed diabetes The only outstanding acromegalic feature was a folding of the skin of the head and extremities These results lend strong support to the generally accepted view that gigantism and acromegaly in human beings are due to over-secretion by the anterior lobe of the pituitary gland

The gonad stimulating hormone (or hormones) is responsible for the normal development and maintenance in a state of functional activity of the sex glands, with the accessory organs and secondary sex characters. In the female the ovaries themselves respond readily to the hormone, in the male the accessory organs show the most striking effects Immature female rats were used by Evans and his colleagues for the assay of their preparations, injections were made on three days, the vaginal orifice examined on the fourth and fifth days, smears being taken as soon as it had opened, and the animals killed and examined about 96–100 hours after beginning treatment.

---

* The Growth and Gonad-Stimulating Hormones of the Anterior Hypophysis By H M Evans, K Meyer and M E Simpson, in collaboration with A J. Szarka, R I Pencharz, R E Cornish and F L Reichert Memoirs of the University of California. Vol 11. Pp 446 (University of California Press Berkeley, California, 1933)

The hormone was prepared from ox anterior lobe (a poor source), from the serum of pregnant mares (a good source), and from the urine of pregnant women. The acetone powder from the alkaline extract of anterior lobes is dissolved in water and the reaction of the solution adjusted to give maximum precipitation: *the greater part of the hormone* remains in solution and is precipitated by flavianic acid, which can be removed afterwards by use of alcohol-ammonia mixture. Alternatively, the powder may be extracted with 50 per cent pyridine, 50–60 per cent alcohol or acetone containing 2–4 per cent ammonia, the hormone is then precipitated by increasing the alcohol or acetone to 85 per cent and adding a little acetic acid or salt. Pregnant mare serum was treated directly with acidified acetone and the powder purified by the methods used in the case of preparations from anterior lobes. From the urine of pregnant women the hormone (called prolan by Aschheim and Zondek its discoverers), was precipitated by excess of alcohol. The precipitate was extracted with dilute acid and the prolan reprecipitated with alcohol, the powder was purified by extraction with acetone-ammonia mixture. The minimum dose of the purest preparations was about 0·05 mgm.

Although preparations from these different sources all stimulate the gonads, yet they show differences in their chemical properties and biological effects. Prolan, for example, is more sensitive to both acid and alkali than preparations from pregnant mare serum; the latter, but not the former, give off hydrogen sulphide on treatment with alkali. However, the differences in chemical properties may be due to differences in the associated impurities. Differences in the biological effects produced are not so easily explained. Even though the minimal doses of different preparations may be the same, larger doses may have widely different effects on the ovary: thus increasing the dose of prolan increases the size of the ovaries at most four times, whilst with preparations from pregnant mare serum, there is a rough proportionality between dose and size up to about twenty-five times the minimal dose.

Evans and his co-workers have not been able to separate the gonad stimulating hormone into follicle stimulating and luteinising factors, corresponding to the *prolans A* and *B* of Aschheim and Zondek. A solution which is predominantly follicle stimulating at one dose level may produce corpora lutea at another level or when the injections are continued beyond the usual three-day period, the predominant effect may depend on the amount of purification to which the extract has been subjected. The type of response also depends in part on the time at which the examination is made after beginning the injections. There are indications that the presence of corpora lutea inhibits further development of the ovary: the occurrence of ovulation depends on the size of the ovary and the dose given. Hypophysectomised female rats were less sensitive than normal animals and the response to prolan was much less than that to extracts of pregnant mare serum; simultaneous administration of the growth promoting hormone diminished the response. Substitution therapy failed to induce the rhythmic changes in the vagina characteristic of the œstrous cycle, a continuous œstrous reaction only being obtained. Pregnancy was not observed owing to failure of implantation, but it could be maintained in animals, hypophysectomised after implantation, by injection of mixtures of growth- and gonad-stimulating hormones.

In hypophysectomised female dogs, prolan had no effect on the genital system even in large doses, and when the system showed a marked degree of atrophy, an anterior lobe extract also had no effect. A mixture of the two preparations, however, stimulated the genitalia within ten days; the vulva increased to a size greater than that observed in normal œstrus in a litter mate control, the mammary gland and uterus showed marked development and the ovary was much enlarged and contained many corpora lutea. This result may be contrasted with some experiments on the hypophysectomised ferret recently published by M. K. McPhail (*Proc. Roy. Soc.*, B, 114, 128; 1933). Anterior lobe extract alone produced extensive theca luteinisation of small follicles, but no development of large follicles: prolan alone caused many follicles to undergo partial growth, which, however, terminated in atresia: the vulva showed partial œstrous swelling. A mixture of the two preparations produced usually only theca luteinisation.

Without referring to other work in detail, it may be stated that several workers in addition to Aschheim and Zondek have adduced evidence that the follicle stimulating and luteinising hormones from the anterior lobe are separate entities. The synergistic action with prolan may depend on the proportions of these factors present in different preparations. Apart from the chemical difficulties of preparing the hormones in a pure state, the facts that they act in succession, or if really a single entity initiate a series of reactions, introduces a complication into the evaluation of the biological tests, which only further work with a standardised technique can clarify.

In immature male rats, doses of gonad stimulating hormone sufficient to produce enlargement of the ovaries in immature females produced little or no increase in the weight of the testes, although the accessory organs grew markedly and attained the size characteristic of these organs in young adults. Larger doses of hormone, however, increased the weight of the testes. Senile males also responded by increase in weight of the accessory organs. In hypophysectomised males injections of the hormone caused regeneration of the atrophied testes, the seminal vesicles became enlarged and filled with fluid and spermatogenesis was resumed; the replacement therapy was complete since normal litters were sired, and the testes appeared normal on histological examination

The atrophy of the thyroid and adrenal glands after removal of the pituitary was not repaired by injection of gonad stimulating hormone, but extracts containing the growth hormone maintained or restored the weight of these organs, although histologically the normal structure was not completely regained Evans's results do not show whether it is the growth hormone or some other active principles in the extracts which are responsible for these effects The cachexia commonly observed in hypophysectomised rats was also relieved by injections of the growth hormone.

The data on which the workers in the University of California base the conclusions briefly reviewed above are available in detail in the monograph now under notice The methods described should be of value to other investigators and their results should form the basis of further research in this important field

The British Association Tables of Bessel Functions

IN 1888 a Committee was appointed by the British Association for the purpose "of considering the possibility of calculating tables of certain mathematical functions, and, if necessary, of taking steps to carry out the calculations, and to publish the results in an accessible form" The Committee had the late Lord Rayleigh for chairman, and 'Mr ' A Lodge for secretary, and the other members were 'Sir W Thomson', Cayley, Price, Glaisher, Greenhill and Hicks Bessel functions were among the functions considered, and their calculation became the chief work of the Committee. Tables appeared in the Reports of the Association for 1889, 1893 and 1896 In 1907 the Committee reported on "The further tabulation of Bessel functions", and in 1909 stated that it was "also considering the advisability of collecting all existing tables of Bessel functions and publishing them in a form easily accessible to all students" During the next few years tables of Bessel functions of various types appeared regularly, and in 1915 it was reported that "the order of calculation is being arranged in accordance with the real urgency of the tables, and the stage is now coming in sight at which the Committee will be able, as authorised already by the Association, to publish a volume of fairly complete tables of the more important transcendental functions".

The Committee's hopeful plans, like others, were, however, hurled to emptiness, and although the Committee remained in existence and many tables were printed in its reports, it was not until after the Glasgow meeting of the Association in 1928 that the preparation of the long foreseen volume was taken seriously in hand; and when in 1931 a volume appeared, it contained no tables of Bessel functions. The reasons for this, and the problems confronting the Committee, were explained in the preface:

" . . It was apparent from the first that the simple plan of reprinting existing material would produce a volume neither useful nor creditable There were gaps in the ranges of the arguments of some of the functions, natural when the tabulation had been performed at different times for special purposes, but intolerable if tables were to be issued for general use. In the case of the Bessel functions, the functions tabulated did not form in any sense a complete collection. Lastly, the original tables offered no facilities for interpolation Two years ago the Committee decided that these difficulties must not impede publication indefinitely, and that, if the Bessel functions were reserved for an independent volume, definite progress could be made "

Since 1929, therefore, the work on Bessel functions has been independent both of the preparation of volumes of tables of other functions and of the computation from time to time of special tables in response to current demands The aim of the Committee is to publish as complete and uniform a set of tables of Bessel functions as possible, the majority will be derived from the reports, but several will be new It is estimated that the tables will extend to nearly five hundred pages, and it is proposed to issue two volumes, partly to avoid an unwieldy book and partly to expedite publication The material for the first volume is in an advanced state, more than three-quarters of the estimated 280 pages being ready for the printer

Unfortunately, financial difficulties have now to be overcome It is not to be expected that an undertaking of this sort can be a paying proposition The mathematicians concerned have given their services, but the mere cost of production will be between 30*s* and £2 a page The calls on the British Association are far more miscellaneous, far more extensive, than in the spacious days when £500 could cheerfully be voted for a single object At the moment, a sum of £150, which includes a grant of £50 from the Royal Society for this purpose, has been set aside by the Council of the Association, but this is little more than an earnest of belief in the Committee's plan Unless further help is forthcoming, there is a serious danger that the enterprise to which a multitude of volunteers have given their leisure during nearly half a century will be completed by the enthusiastic drudgery of the Committee which has accepted it as a heritage, only to rest—a manuscript almost too precious to be consulted—in a fire-proof safe. It ought to be sufficient, by directing attention to this possibility, to ensure that funds will be provided to enable the two volumes to be published and thus to make available the results of so many years of voluntary work on behalf of mathematical students and others.

Effect of Low Temperatures on Metals

SINCE the year 1905, when Sir Robert Hadfield and the late Sir James Dewar described the effect of liquid air temperatures on the strength of iron and its alloys, there has been not only a very considerable advance in low temperature technique, but also many types of new metallurgical materials have been successfully developed Many alloys which are to-day in extensive use as parts of machines and structures were quite unknown at the time of that research

The importance of low temperature research was recognised many years earlier than 1905 in view of the severe winter conditions experienced in northern Continental lands In research work of the future, still greater attention is likely to be paid to the study of low temperature phenomena in relation to the physical and engineering sciences

Recently Prof. W J de Haas and Sir Robert Hadfield[*] have described to the Royal Society the results of a further important research on the mechanical properties of these materials at the boiling point of liquified hydrogen (–252 8° C) This work has extended the range of study of the properties of metals a further 60° C and thus the strength of these metals is now known at 20 3° K At this low temperature, changes in the properties of some of the metals have occurred, but the present work does not show any marked discontinuity in general properties corresponding to the sudden fall in electrical resistivity which exists in some metals near to the boiling point of liquid helium The possibility of the use of liquid helium has for the moment been postponed on account of the large quantities that would be needed to effect cooling If its use is later found to be practicable, tests would be made as low as 4 2° K On small specimens a study was made at this temperature in 1921 in collaboration with the late Prof Kamerlingh Onnes and H R Woltjer In those experiments they showed the absence of magnetic transformations in the iron-manganese alloys, whereas the iron-nickel alloys exhibited the presence of polymorphic transformations

Prof de Haas has designed the testing apparatus for this work, immersing the specimens in liquified hydrogen contained in a Dewar flask. The testing stress has been applied by an oil cylinder through a tension rod sliding inside a concentrically mounted tube Into the ends of these two members the specimen holders have been fitted

The specimens selected for examination not only included the materials which had previously been tested in liquid air, but also many recently developed alloys which exhibit a combination of high strength and ductility.

At liquid air temperatures, many ferrous materials, including iron itself, show a marked increase in tenacity, and in general these same ferrous materials show a continued fall in ductility, which becomes negligibly small at the boiling point of hydrogen At this temperature there is an apparent fall in strength There are, however, some remarkable exceptions to this fact, for example, an alloy containing 6 per cent of manganese and 24 per cent of nickel shows an increase of ductility when cooled to –194° C , and on being further cooled to the boiling point of hydrogen, it still retains appreciable ductility This present work thus continues the study of the iron-nickel-manganese-carbon alloys which were described in the seventh report to the Alloys Research Committee of the Institution of Mechanical Engineers in 1905

The 'stainless steels' and 'high temperature alloys' are two classes of materials which are not adversely affected by fall of temperature , for example, the well-known alloy containing 18 per cent of chromium and 8 per cent of nickel shows the remarkable strength of 119 8 tons per square inch, accompanied by an elongation of 25 per cent

The non-ferrous alloys which the authors have selected are all ductile at the lowest temperature of test The earlier work had shown that nickel, copper and aluminium increased in strength without a corresponding fall in ductility In the present tests, the copper specimens break at 29 7 tons per square inch accompanied by a ductility of 60 per cent in extension, but a bronze, containing 10 per cent of tin, shows a slight reduction in properties Good extension occurs during test of specimens of an '80/20' nickel-chromium alloy and of the aluminium alloy known as 'duralumin' The safety of the aluminium alloy from embrittlement will be a guidance to designers of aircraft

A consideration of the non-ferrous alloys selected for test shows that these possess a lattice structure of the face-centred cubic type which appears to allow the retention of ductility at low temperatures, but in ferrous alloys this arrangement of the atoms is not always accompanied by ductility ; for example, the toughened manganese steel and the low carbon alloy of this metal with iron, are not ductile, although their structures conform at normal temperatures to the face-centred form of the cubic system The embrittlement of austenitic manganese steel appears to be entirely unaccompanied by metallographic change of a permanent character, for the material reverts to a ductile state at normal temperatures On the other hand, austenitic nickel steels show a change which is irreversible.

The iron alloys of the ferritic type have a body-centred lattice and are not ductile at low temperatures These materials contrast very strikingly with the austenitic 'stainless' and 'heat-resisting' steels, which possess a face-centred cubic structure and are not embrittled

Obituary

PROF. ALBERT CALMETTE, For Mem R S

ALBERT CALMETTE, sub-director of the Pasteur Institute, who died on October 29, 1933 after a short illness, was born at Nice on July 12, 1863 After graduation, he entered the medical service of the navy and spent seven years in Eastern waters As a naval surgeon, he became interested in the numerous hygienic problems of France's colonial possessions In 1889 he was transferred to the new colonial medical service and was given permission to go to the Pasteur Institute There he came under the influence of Pasteur, and took Roux's course of lectures in bacteriology and became one of his most enthusiastic pupils His progress was so rapid that the next year he was chosen by Pasteur to proceed to Saigon to found the first of the daughter Pasteur institutes

At Saigon, Calmette was occupied with the study of cholera and bacillary and amoebic dysenterics It was here, too, that he first became interested in snake venoms The number of deaths from cobra-bite was serious and the director of the new institute was appealed to for help by the administration

In 1893 Calmette returned to France and continued his work on the action of cobra venom This was followed up by experiments to ascertain whether the serum of an animal immunised against the venom contained anti-toxins and could be exploited for treatment Sewall had shown that immunity followed repeated small injections of the venom of the rattlesnake, and Behring had a few years previously established the anti-toxic value of the serum of animals treated in a similar manner with the toxins of the tetanus and diphtheria bacillus It seemed, therefore, not unlikely that an anti-toxic immunity would be aroused by the injection of snake venom

Before the end of 1894 Calmette was successful in demonstrating that by patiently immunising horses with increasing doses of cobra venom they accumulated sufficient antitoxin in their serum for the latter to be used as a remedy for snake-bite As most venoms were similar in their actions, Calmette at first supposed that serum prepared by injecting cobra venom would be of value to counteract the effects of the poisons of other kinds of snake. He was rather obstinate in adhering to this opinion in the face of experimental evidence from Australia, India and Brazil that such was not the case but that anti-venoms were highly specific.

In 1895, Calmette's enthusiasm and organising ability was again taken advantage of and he was chosen to establish a Pasteur Institute for the north of France at Lille The new institute was to be a subsidiary centre for anti-rabic inoculation and the preparation of diphtheria antitoxin and vaccine lymph. Under Calmette's guidance, it soon became an active centre of research. From the point of view of sanitation, the industrial town of Lille was not progressive Its water supply and methods for the disposal of sewage were unsatisfactory The incidence of tuberculosis was high and invalidism from hook-worm in the neighbouring coal-mines was serious Calmette, who was appointed professor of hygiene a few years after his arrival, worked vigorously to improve the sanitary condition of the town He instituted investigations into the bacterial treatment of sewage and various methods for the purification of water supplies He was successful in inducing the municipal authorities to undertake some measure of improvement He made a useful research into hook-worm, and his method for combating this disease in miners is that now usually followed elsewhere

How to diminish the damage to health and life caused by infection with the tubercle bacillus was a more serious problem Calmette established a tuberculosis dispensary, the first in France, for the early diagnosis of phthisis and for the education of patients in habits to minimise the familial spread of the disease He was instrumental in providing a sanatorium for early, and a colony for advanced, cases of the disease These measures, however, did not strike at the root of the matter and the idea of attacking the problem by some immunological procedure was always present in his mind All efforts to produce resistance by the inoculation of killed cultures of the tubercle bacillus having proved unsatisfactory, he turned his attention to the possibility of employing a living attenuated culture as Pasteur had done in the case of anthrax His goal was to produce a strain of the bacillus so much deprived of its virulence that it would not produce tuberculosis when introduced into animals but only a mild illness, recovery from which inevitably occurred It was hoped that by this experience the body would acquire the power of dealing satisfactorily with a subsequent infection by virulent microbes

In 1903, in collaboration with his assistant Guérin, Calmette began the researches which ultimately resulted in the now famous strain of bovine tubercle bacilli designated B C G (Bacillus Calmette Guérin) This strain was produced by successive propagation of an ordinary bovine type of bacillus on potato soaked in bile Its stabilisation took thirteen years, during which 230 successive cultivations were made. At the end of this time, the strain was found to be incapable of producing tuberculosis in animals and to remain devoid of this power as long as it was cultivated on the bile-media

By 1914 the experiments of Calmette and Guérin had convinced them that cultures of B C G. could be used to induce resistance to tuberculosis in cattle. At this stage, their researches were perforce suspended by the outbreak of War. During the occupation of Lille, Calmette came under suspicion because he kept numbers of pigeons in his laboratory. He suffered regrettable indignities at the hands of the military authorities and his wife was removed to Germany as a hostage. During this unhappy period, he occupied himself writing an interesting book on the pathology of tuberculosis, in which he presented his observations and developed his theory of the nature of acquired resistance to the disease.

On the death of Metchnikoff in 1917, Calmette was elected sub-director of the Pasteur Institute but did not undertake the duties of this office until after the War. At Paris he continued his researches on protection against infection by the tubercle bacillus with increased fervour and enlarged opportunities.

To understand the subsequent progress of these researches it is necessary to epitomise his conception of the means by which individuals acquire their resistance to the tubercle bacillus. Both evidence from post-mortems and the results of the skin reaction of von Pirquet to tuberculin indicate that the majority of individuals by fifty years of age have at some time in their life been infected, although they may not have shown symptoms of tuberculosis. Calmette believed, and had experimental evidence to support his belief, that a very small number of infecting bacilli is not, in most individuals, followed by manifest tuberculosis and is recovered from, leaving the body more capable of resisting a subsequent dose. In this manner by a succession of small infections an immunity is acquired.

Immunisation by chance is, however, a highly dangerous way of attaining resistance, for, at any time, the dose may be sufficiently large to break down the individual's resistance and tuberculosis ensue. Calmette therefore advocated that the wise procedure would be to accustom the body to resist invasion by the tubercle bacillus by giving its immunological mechanisms opportunities to obtain practice with an innocent tubercle bacillus before the nearly inevitable inroad of a virulent one took place, much as it is well to acquire expertness as a toreador with de-horned cattle. To do this he suggested that young babies should be given minute doses of his attenuated B C G. culture by mouth before they have had an opportunity to ingest virulent bacilli, a procedure he calls 'premunition'.

In 1922 Dr. Weill-Hallé treated 314 infants, the progeny of tuberculous mothers. The treatment was inoffensive and a comparison of the tuberculosis rate amongst treated and untreated infants from similar environment was deemed to be promising. The treatment was begun 3 days after birth to minimise the chances of the infants being infected by virulent bacilli from their mothers prior to receiving the strain B C G. Since then upwards of a million babies have been treated in France and elsewhere, and apart from the tragedy at Lubeck, where by carelessness at the hospital, some 250 infants were fed a dose of a culture of virulent human tubercle bacilli by mistake and 73 died, no untoward happening has been recorded. At the present time some 150,000 infants are treated annually in France alone and the council of the Pasteur Institute has erected a vast building for the preparation and distribution of cultures of B C G all over the world.

Unfortunately, the resistance obtained from one treatment is not permanent and has to be repeated after one or two years. This makes it more difficult accurately to assess the results of the treatment for some years to come. The figures recorded are susceptible of statistical criticism, but the numerous practitioners who have employed the treatment are very generally convinced that it is followed by a decline in the incidence of tuberculosis and also by a diminution of the general mortality during the early years of life. To what extent this promise is justified will emerge in a few years, when the after-history of the million infants already treated is known. Whatever this verdict is, Calmette's endeavours to mitigate the ravages of tuberculosis will remain the magnificent effort of a man who devoted his life to the pursuit of science for the service of mankind. C. J. M.

MR. J. B. HOBLYN

By the death on December 24 of John Bright Hoblyn, in his fifty-fourth year, the automobile engineering industry has lost one of its best known scientific personalities. During his eighteen years' association with Messrs. Vauxhall Motors Ltd., of Luton, he had become a prominent figure in the fields of metallurgy and petroleum technology, and his ready flow of witty and pungent speech—and, on occasion, of scathing criticism—made him an attractive lecturer and debater.

An old student of the Royal College of Science, Mr. Hoblyn was for eleven years science master at Luton Modern School. In 1915 he accepted an invitation to join Vauxhall Motors Ltd. as chief chemist and metallurgist, and he promptly applied himself to the chemical and metallurgical problems of automobile engineering. His publications included three papers of outstanding importance to the industry, dealing respectively with the heat treatment of steels, the oxidation of lubricating oils and the development of aluminium alloys for automobile construction. His work on lubricating oils opened up a new avenue in the testing technique of these products.

For several years past Mr. Hoblyn had been chairman of the committee set up by the Institution of Automobile Engineers for the rationalisation of automobile steel specifications, and at the time of his death he had almost seen the completion of his labours in this field. L. B. H.

We regret to record the death of Prof. J. E. G. de Montmorency, Quain professor of comparative law in the University of London in 1920–32, whose studies of primitive law formed valuable contributions to anthropology, on March 9, aged sixty-seven years.

News and Views

Gottlieb Daimler (1834–1900)

ON March 17 the centenary occurs of the birth of Gottlieb Daimler, the distinguished German engineer, to whom we owe the introduction of the light high-speed spirit engine suitable for road vehicles. After a varied practical experience as a mechanical engineer, Daimler in 1872, at the age of thirty-eight years, became associated with Langen and Otto, who were then engaged on the improvement of the gas engine, and Daimler's own contribution to the progress of the internal combustion engine is but an illustration of how invention begets invention. His death took place thirty-four years ago, before motor-cars had ceased to be novelties in the streets, but of the millions of cars to-day every one owes something to Langen, Otto and Daimler and their collaborator, Maybach. Daimler was born at Schorndorf, Wurttemberg, and at the age of nineteen years began work in a machine tool factory. From 1857 until 1859 he was a student at Stuttgart Polytechnic; from 1861 until 1863 he worked in England and then held positions in works at Geislingen and Karlsruhe. The turning point in his career came when in 1872 he joined Langen and Otto as technical manager of the Gasmotorenfabrik Deutz A.G., near Cologne. The firm had already achieved considerable success with its atmospheric gas engines and Otto was engaged on the experiments which led him to the invention of the four-stroke engine, patented on August 4, 1877, and to the manufacture of the world-famous 'Otto' gas engines.

IN these developments Daimler played an important part, and visualising the possibility of applying internal combustion engines to vehicles, in 1882 he left the Deutz concern and with his friend and colleague, Wilhelm Maybach, set up an experimental workshop at Cannstatt. By August 1883 he had built a four-stroke engine using benzine, running at 900 r.p.m., and on December 16, 1883, he took out his patent. He next proceeded to fit high-speed engines to a form of bicycle, to a four-wheel carriage and to a boat. By this time, Karl Benz of Karlsruhe had also produced a motor-driven three-wheel vehicle, and it is thus to this group of German engineers that the world owes the birth of the motor-car. The Benz cars, the first to be made in any considerable numbers, were exploited in Paris by E. Roger, while the manufacture of Daimler cars was taken up by Panhard and Levassor, whose early design, with the engine in front, has been followed generally ever since. After selling the French rights to the use of his patents, Daimler in 1890 founded the Daimler-Motoren-Gesellschaft at Cannstatt, of which for a considerable time Maybach was the manager, Daimler acting chiefly in an advisory capacity. Daimler's death took place at Cannstatt on March 6, 1900. Two years later, the Württemberg branch of the Verein Deutscher Ingenieure placed a memorial to him in the gardens at Cannstatt where, in 1885, Daimler had driven his first automobile.

Sir James Hector (1834–1907)

SIR JAMES HECTOR, the first director of the Geological Survey of New Zealand, a post he held from 1865 until 1905, was born at Edinburgh a century ago on March 16. The son of a writer to the signet, he was educated at Edinburgh Academy and the University and in 1856 took the degree of M.D. After acting for short periods as assistant to Edward Forbes and Sir James Simpson, in 1857 he was, through Murchison, appointed surgeon and geologist to Capt. John Palliser's expedition to British North America. During this expedition he discovered Hector Pass in the Rocky Mountains and directed attention to the evidence of glaciation and the existence of erratic blocks. In 1860 he sailed for New Zealand to take up the appointment of geologist to the Government of Otago. The services of von Haast (1824–87) and von Hochstetter (1829–84) had already been secured by the colonial authorities, and it was by these three men, together with J. W. Hutton (1836–1905), that the geology of the Islands was first unravelled. In 1865 Hector became director of the Geological Survey and of the Colonial Museum at Wellington, which remained his headquarters for the rest of his life. He was also head of the meteorological service and Chancellor of the University of New Zealand. Elected fellow of the Royal Society in 1866, he was awarded the Lyell medal of the Geological Society in 1875 and in 1887 was made K.C.M.G. In 1891 he served as president of the Australasian Association for the Advancement of Science. He died at Wellington on November 5, 1907.

The Mentality of the African

MR. A. T. LACEY's opening statement in the discussion on "The Genius of the African" which took place at the meeting of the Education Circle of the Royal Empire Society on March 8, gave a clear view of the fundamental factors in the problem which awaits solution in the development of African peoples. As Director of Education in Nyasaland, Mr. Lacey has had an excellent opportunity of forming an estimate of the capacity of a good, but not exceptional, sample of the Bantu peoples, and his conclusions, which recognise the native's limitations without unduly stressing his failings, deserve the careful consideration due to an opinion based on an intimate knowledge of conditions and a clear perception of the forces which make the present moment a critical period for the future of the greater part of Africa. Mr. Lacey agrees with other students of present-day tendencies in Africa in diagnosing the essential element of the problem as a conflict between the mentality of a people whose whole outlook is conditioned by group consciousness and group responsibility, and the type of mentality which is produced by the individualism of a European economic and social organisation. He pointed out that with the native's traditional outlook goes a spontaneous observance of law and order; but to maintain this disciplined attitude in changing conditions and to meet the new individualistic attitude, the group or tribe must now find a new orientation. As an educationist, he, not unnaturally, pins his faith to the individual; and he, therefore, proceeded to demonstrate the educability of the African from the degree and character of the achievement of the natives under his jurisdiction. In rating it relatively high, he is in agreement with others whose acquaintance with the African is not less than his own.

In view of Mr. Lacey's remarks on the place of the family and tribal group in promoting the maintenance of law and order, it is a disappointment to find that he anticipates little assistance from the home environment in the slow process of building up an educational tradition. The pre-European system of native education was largely left to the influence of the social environment, and if the group should attain the new orientation which is said to be a necessity of future development, it should be made to play its part in developing the social consciousness of the rising generations, co-operating with the more academic influence of the official system of education. It is evident that a grave responsibility will rest on the administration in guiding tribal development towards the new orientation along lines which avoid any sudden break with tradition and yet lead towards the full social and religious life which Mr. Lacey postulates as an inspiration for the full expression of the Bantu genius. In this connexion the article on "Kenya Cults" which appeared in the *Times* of March 10 is suggestive. The author of that article describes some of the strange cults which have arisen recently in Kavirondo and among the Kikuyu. Their appearance in Kenya is not unique, but can be paralleled by strange forms of belief which have been grafted on Christianity and have attracted a large number of followers from time to time in other parts of Africa, and it will be remembered that it was a dispute, similar to that now described, but on a much larger scale, between the followers of Roman Catholic and Protestant creeds which first led to European intervention in Uganda. It is suggested by the writer in the *Times* that the Kenya cults are matters for the anthropologist rather than the administrator, but against this view, it is a question whether, owing to the tendency of the African towards fanatical adherence to aberrant and anti-social cults, the attitude of the administration towards developments in native religion does not require fundamental revision.

24-Hour Time System

It has been announced that the British Broadcasting Corporation will adopt at an early date the 24-hour system of expressing time. The system will be used in announcements over the microphone, in the journals issued by it and in correspondence. This decision by the B.B.C. will provide the best possible opportunity of testing whether the general public is in favour of or is opposed to the 24-hour system. Though the adoption of the 24-hour system has been widely supported by transport organisations (rail, road and air), by engineers, by the mercantile marine and in scientific circles, the Government has taken the view that there is no very strong demand for the change and that it would be wrong to impose upon the public a system of notation which might confuse rather than assist. As was announced in NATURE last week (p. 354), the Postmaster-General has stated that he proposes to await the result of the B.B.C. experiment before coming to a decision. It was apparently with the same desire to see what measure of support or opposition from the general public was indicated that the House of Lords on March 7 negatived a motion introduced by Lord Lamington urging that the 24-hour system should be put into operation as soon as possible, though the House on December 7, 1933, had approved a motion for the adoption of the system.

Development of the Royal Air Force

Presenting the air estimates to Parliament on March 8, Sir Philip Sassoon, Under-Secretary of State for Air, outlined a programme of expansion of the R.A.F. which, while modest, is probably as large as can be undertaken with efficiency at the present time, remembering that previous economies have restricted both the training of personnel, and the provision of accommodation for additional squadrons. The net amount provided is £17,561,000, an increase of £135,000 over last year's figure. If grants from India and the Admiralty in respect of R.A.F. services to them are added, these figures become £20,165,000 and £527,000 respectively. Four new squadrons are to be formed, two for home defence, one flying boat squadron, and the equivalent of one squadron for the Fleet air arm. In addition, two home defence squadrons, at present forming part of an experimental station, and consequently non-effective as fighting units, are to be reconstituted as active squadrons. The principal increased expenditures are obviously to be made under Votes 3 (technical equipment), and 4 (works, buildings, lands, etc.). It is interesting to note that Vote 2 (non-technical stores) remains stationary, in spite of the expansions, due to lower prices. Vote 8 (civil aviation) stands at the highest figure for the last ten years. This includes expenditure upon the British Government part of the route to Australia, up to Singapore, the first link of the Atlantic service, New York to Bermuda, and the usual subsidies for flying activities in Great Britain. Sir Philip also gave an interesting account of the various developments of the R.A.F., including long distance communication flights, police duties and distress relief in remote lands, air surveying, etc. The use of petrol produced from British coal has been successful, and it is hoped to maintain seven squadrons upon it exclusively during the coming year.

Elements Old and New

In a lecture with the above title given at East London College on March 8, Prof. James Kendall, of the University of Edinburgh, traced the development of fundamental ideas on the elements from the earliest times to the modern period. The four elements of the Greek philosophers—fire, air, earth and water—expanded during the nineteenth century into ninety-two elements of the periodic system, and all these ninety-two are recognised now to be aggregates of two simpler electrical units—positively charged protons and negatively charged electrons Nevertheless, it is interesting to note that chemistry, in its development as a science from alchemy as an art, has passed through four distinct stages, in each of which one of the four elements of Aristotle has been dominant (see NATURE, March 10, p 354)

JUST as atmospheric air was found by Raleigh and Ramsay to contain traces of unsuspected elements—argon, neon, krypton and xenon—so ordinary water has recently been shown to have present in it a minute quantity of a novel compound—*heavy water*. Each hydrogen atom in heavy water comprises two protons and two electrons, or twice the quota of an ordinary hydrogen atom, and this increased complexity involves a significant change in chemical as well as in physical properties Pure heavy water, prepared by a series of fractional electrolyses, has a density more than ten per cent higher than that of ordinary water It freezes at 3 8° and boils at 101 6° C. It retards the development of plant life, and proves fatal to certain lower species of animal life, such as tadpoles and flat-worms What its effect, in pure and diluted form, upon the human organism may be is at present merely a matter of interesting speculation. A very interesting survey was given of the views held on the nature of the elements from the earliest period to the present day, and Prof Kendall suggested that in the future a further phase of development, corresponding with the fifth element of Aristotle, the quintessence or the ether, which survived the other four elements by a century, might recognise the greater importance of radiant energy in chemical processes.

Accidents and their Prevention

A CHADWICK public lecture on "The Causes and Prevention of Human Accidents" was delivered by Dr C. S. Myers, principal of the National Institute of Industrial Psychology, on March 12 Hitherto accidents in factories and on the road have been too often attributed merely to recklessness and carelessness and to dangerous conditions More than 50 per cent of factory accidents (fatal and non-fatal) are found not to be due to dangerous machinery; and it has been estimated that, however much better machinery be guarded, the present factory accident rate of more than 106,000 per annum is unlikely to be seriously reduced by these measures or by more extensive use of safety-first posters. On the road, in spite of improved signals, car controls, regulated speeds of traffic and better lay-out of roads, 216,000 were injured and more than 7,000 killed in Great Britain through car accidents in 1933. At least 80 per cent of all such fatal accidents are attributable to the 'human factor', the study of which in occupational life is the concern of the industrial psychologist. Accidents are not uniformly spread over the population whose actions may give rise to them. In each of two American investigations, it was found that about a half of the total accidents incurred by trams and omnibuses were confined to about a third of their drivers In England, the scores obtained in selection tests for the motor driver devised by the National Institute of Industrial Psychology, have proved to be so highly correlated with the records of the safe driving of motor drivers on the roads, that one well-known insurance company has recently offered a ten per cent reduction in the annual premium for accident insurance to those who have passed these tests satisfactorily Selection methods, however, must be supplemented by adequate knowledge, which can be obtained only by systematic training

New Land in the Antarctic

CONSUL LARS CHRISTENSEN, the Norwegian whaling expert who has done much to encourage Norwegian exploration in the Antarctic, left Cape Town in the whaler *Thorshavn* in December last year for the south He has now returned to Montevideo and, according to the *Times*, announces the discovery of a new stretch of coast line 150 miles in extent, in lat 72° S Unfortunately, the longitude is not given but the land would seem to lie in the unknown sector south of Bouvet Island between Princess Ragnhild Land on the east and Crown Princess Martha Land on the west The hypothetical coastline was there drawn in approximately the latitude of the new discovery, which has been named Princess Astrid Land A further note in the dispatch in reference to soundings in deep water on the supposed site of land suggests that some earlier discoveries may have to be moved south, but no details are yet available

A New Antarctic Expedition

IT is announced in the *Times* that a British Antarctic Expedition will leave England in September for the western side of Graham Land It will be led by Mr J. R Rymill, of the recent Watkins Greenland expedition, who will be accompanied by fourteen men most of whom have had experience in Greenland. They include Messrs. W E Hampton, Q. Riley, A Stephenson, and E Bingham A vessel of about 120 tons, to be manned by the members of the expedition, will sail via Deception Island in the South Shetlands to Wilhelmina Bay in North Graham Land whence, after a reconnaissance by aeroplane, a sledge journey will be made along the east coast to Crane Channel and back Later in the summer, the ship will be taken farther south and a base for two winters will be sought in Marguerite Bay, or farther south in Graham Land or possibly Hearst Land. If a safe harbour cannot be found, the ship will return to Deception Island leaving most of the expedition at a land station From the southern base a sledge journey will start eastward in October 1935, returning about March 1936. It is hoped that this journey will settle the problem of the western coast line of the Weddell Sea In the following summer, sledge journeys, supplemented by aeroplane flights, will be made westward to Charcot Island and beyond if possible. The expedition hopes to return to England in May 1937. This ambitious project, which should solve some of the outstanding problems in Antarctic discovery, is estimated to cost no more than £15,000, of which the British Government is giving £10,000 and the Royal Geographical Society £1,000

Sir Everard im Thurn Memorial Scholarship

THE council of the Scottish Anthropological Society proposes to create a permanent memorial of the late Sir Everard im Thurn by founding a lectureship in anthropology Sir Everard im Thurn was the first president of the Edinburgh and Lothians Branch of the Royal Anthropological Institute, an office which he held from 1924 until 1932, and was one of the first to advocate the formation of a Scottish national society for the advancement of anthropological teaching and research Sir Everard's distinction as an anthropologist has been widely recognised He was the author of the standard work on the Indians of Guiana, contributed numerous papers on anthropological subjects to scientific journals, and was president of the Royal Anthropological Institute in 1919–21 It is intended that the Sir Everard im Thurn memorial lecture should be delivered annually on the date of the annual general meeting of the Society by an anthropologist of note For this purpose, it is stated in an appeal issued by the memorial committee, of which Prof H. J Rose, president of the Society, is chairman, a capital sum of £500 will be required to meet the annual expenses Part of this sum has already been provided, but further subscriptions are invited to make up the amount In the meantime, arrangements have been made for the delivery of the first lecture on May 22, 1934, when Dr R R Marett will lecture on "Sir Everard im Thurn as Anthropologist and as Man" Contributions to the fund should be addressed to the honorary treasurer of the Society, Mr. J B. Mackay, 30 St. Alban's Road, Edinburgh

Work of Geological Surveys

THE presidential address of Sir Thomas Holland at the annual general meeting of the Geological Society on February 16 was mainly devoted to an examination of the organisation of the geological surveys of the British Empire and the United States. He emphasised the fact that the real object of every such survey is the mineral development of the country, scientific results being obtained as by-products and used as a means to attaining the economic object in view. The work of preparing a geological map requires the co-operation of various specialists of at least seven kinds With a director and his assistant, a curator and a chemist, the minimum number of scientific officers required for a survey like that of India, for example, is found to be about 21 Below this standard an organisation is scientifically inefficient and economically wasteful. The colonies separately might not be able, for financial reasons, to maintain this standard, but the difficulty could be partially met, as in the Federated Malay States, by a federation of officers in geographically related groups Important functions of a survey are the classification of public lands and the compilation and analysis of mineral statistics. The director should be well acquainted with the trend of mineral development, watching imports for indications that the country might itself produce certain minerals and by-products He should therefore be the adviser of his Government on questions of mineral policy, whether in purely economic matters or in the development and conservation of minerals that are essential for the production of munitions of war

Science and Society

THE third Hobhouse memorial lecture, on the subject, "Rational and Irrational Elements in our Society", was delivered at Bedford College for Women on March 7 by Prof Karl Mannheim, formerly professor of sociology in the University of Frankfort-on-Main, and now lecturer in sociology at the London School of Economics and Political Science The main theme of the lecture was the problem created for contemporary society through the disproportion between the range of man's technical knowledge, and his moral qualities and rational insight into the social mechanism which it is the task of members of society to control Society must break down unless this grave disproportion be remedied. Owing to the correlation of the growth of certain moral and spiritual elements with certain features in society, the problem is amenable to scientific treatment The question to be answered is what are the elements in an industrialised society which tend to heighten rationality and at the same time to promote irrationality. Two senses of rationality must be distinguished. Substantial rationality relates to thinking and understanding, to the cogitative elements in general; functional rationality relates to the organisation of activities for the attaining of given ends calculated from the point of view of a given observer. Modern industrialised society has revealed the power to plan and control possessed by those who are emotionally primitive. Our society is faced with the problem of planning the man who has to plan men. Its future depends upon the group within society which has the ability to control, and the energy to subdue the irrational elements

Birmingham Museum

THE City of Birmingham Museum and Art Gallery, which celebrates its jubilee this year with a series of special exhibitions, the first of which was opened on February 24, may be said to have had its origin in the presentation of Edward Coleman's painting, "Dead Game", by a body of subscribers in 1864, an Art Gallery formed in a room of the Free Library being opened to the public in August three years later In 1870, £1,000 was raised towards the formation of a Museum of Industrial and Decorative Art, but the establishment of a natural history museum was not mooted until 1887 The project received little support as Dr. Sans Cox had already established a collection at Queen's College, which was later handed over to the corporation. In 1904, however, the City Council decided to allocate the upper floor of the new Art Gallery building, facing Congreve Street, for a natural history museum.

The principal gifts that followed were the Blatch collection of Lepidoptera, presented by Sir George Kenrick, a collection of British and foreign bird-skins by Mr. Walter Chamberlain; the Scott collection of British birds and foreign Lepidoptera, from Mrs. Adrian Hope and Mrs. Farnham, the Bradley collection of Hymenoptera, Diptera, Lepidoptera, etc., from Mr. A. R. Hollinsworth, the herbarium of British plants from Mr. J. E. Bagnall, a large collection of British and foreign plants from the late Sir Benjamin Stone, the Sir George Kenrick Library of entomological works, the Wilkins' ethnographical works, and numerous miscellaneous collections—a nearly complete collection of British birds (about 1,200 specimens) together with more than 14,000 nests and eggs, and one of the finest series of nestling birds in downy plumage in existence, purchased and presented in 1924 by the Feeney Charitable Trustees, is on exhibition. There is also a collection of British and foreign freshwater and marine shells, formed by the late W. H. Whitlock, and a comprehensive land and freshwater shell collection obtained by the late P. T. Deakin. The scheme for the arrangement of the specimens was drawn up by the late Prof. F. W. Gamble. In addition, weekly nature study exhibits, mainly of a botanical nature, are arranged during the summer months. In 1912, an assistant-keeper for the Natural History Department was appointed.

Award of the Eugenio Rignano Prize

The committee of judges for the award of the Eugenio Rignano prize for the best essay on "The Evolution of the Notion of Time" has recently announced its decision in a "Rapport de la Commission du Jury" dated October 1933. The prize, having a value of 10,000 lire, was established in 1930 as a memorial to E. Rignano, director of *Scientia*, who died in Milan on February 9 of that year. Competing essays were submitted by the end of 1932. No limitations were imposed as to mode of treatment, so that equal scope was afforded to scientific and philosophical aspects of time. A total of 35 essays were submitted, from the following countries: Italy (7), France (6), Germany (6), India (4), Great Britain (2), United States (2), Hungary (2), and one each from Austria, Switzerland, Russia, Luxembourg, South America and Australia. As a preliminary selection of essays of outstanding merit, the committee chose the papers of the following authors: E. Klein, W. Gent, G. Giorgi, H. Mehlberg, K. Sapper, J. Sivadjan, L. von Strauss, G. Windred and S. Zawirski. Of these, Prof. G. Giorgi of the University of Palermo and Prof. S. Zawirski of the University of Poznań were finally selected as *ex aequo* recipients of the prize.

Considerable space is devoted in the "Rapport" to a comparison of the various works submitted, and the widely varying nature of their treatment is remarked upon. The papers of G. Windred and K. Sapper receive extensive discussion in this connexion. Both papers are concerned with the historical development of the subject, but the points of view are respectively scientific and philosophical. The former author confines his attention chiefly to the problem of time as arising in mathematics and physics, tracing the origin and development of the various concepts from the time of Barrow and Newton up to the present day. The treatment of Sapper is essentially philosophical, and mainly concerned with temporal systems such as those developed by Kant and Leibniz, having but few connexions with mathematical or physical theory. These two methods of approach are representative of the widely different points of view of science and philosophy, even upon such a universal concept as that of time.

Recent Advances in Inorganic Chemistry

Lectures, delivered last year before the Institute of Chemistry by Prof. G. T. Morgan, entitled "A Survey of Modern Inorganic Chemistry" have been made available to a wider audience by their publication by the Institute as a pamphlet which extends to more than one hundred pages (London: Institute of Chemistry). The three lectures thus provide chemists with a valuable monograph on the recent advances and tendencies of inorganic chemistry. Prof. Morgan describes, *inter alia*, the discovery and preparation of 'heavy' hydrogen, which some believe will prove so different from ordinary hydrogen as to be regarded almost as a new element, "in which case the organic chemistry of compounds containing this heavy isotopic hydrogen will become a fascinating but fearful study". Mention is made of the newer fundamental units of atomic structure, and attention is given to the electronic conception of chemical valency. The periodic groups of elements are then considered in turn with reference to the experimental successes of recent years in the discovery of new elements, new types of compounds, and new properties. Co-ordination compounds, in view of their general importance and of an interest which has resulted in many contributions to our knowledge of their behaviour having been made by Prof. Morgan and his pupils, receive due examination. The survey in this pamphlet disposes adequately of the suggestion that inorganic chemistry is anything other than a progressive and rapidly growing section of the science, and it is satisfactory that there are evident signs of a renewed interest in this branch of research among British chemists.

North American Earthquakes

Towards the end of January, two violent earthquakes occurred in North America. The first on January 28 at 2.9 p.m. (7.9 p.m., G.M.T.) caused great damage in the Mexican port Acapulco and other towns in Guerrero. From the records at eleven stations, the epicentre is placed by the U.S. Coast and Geodetic Survey in lat. 15° N., long. 99° W. As this point is 140 miles due south of Acapulco, the earthquake must have been of great strength to damage houses in that city. The second occurred on January 30 at 3.16 a.m. (8.16 a.m., G.M.T.). According to the records from seven observatories, the epicentre lay in lat. 38·8° N., long. 118·6° W. This point is in the State of Nevada in the Walker Lake region, and is close to the epicentre of the earthquake of June 25, 1933, and about 50 miles west of that of the great earthquake of December 21, 1932, one of the most violent recorded in the United States (Wire Report, Science Service, Washington, D.C, January 30 and 31).

Pyrex Glass for the 200 in. Reflector

According to a Science Service report, the 200 in. mirror of the new Californian telescope will be made of a sort of pyrex glass and will be poured very shortly. It was at one time proposed to make the mirror of fused quartz, but a superior pyrex glass, which has a small temperature coefficient of expansion, has been developed for the purpose. The glass will be taken from the furnace at a temperature of 1,500° C and poured at about 1,000° C. The cooling and annealing processes will occupy several months The oven for the large reflector has already been used to make a 120 in. flat which will be required to test the larger mirror Preliminary tests for strain have shown that this flat is superior to the excellent 60 in. mirror now used at Mount Wilson. The flat is perfectly clear and almost free from bubbles. The test flat will have the same type of construction as the big mirror, namely, a hexagonal system of ribs, which gives rigidity, and in which nineteen points of support will be provided. Ten supporting levers will be attached in ball bearings so that frictional and elastic distortions will be minimised. The holders will work in any position so that the mirrors can hang upside down if necessary.

Work of International Polar Year Expedition

The Symons memorial lecture of the Royal Meteorological Society will be given on Wednesday, March 21, at 7.30 p.m, by Mr J M. Stagg, leader of the British Expedition which occupied Fort Rae in Canada during the Second International Polar Year, 1932–33. The site of Fort Rae is of exceptional interest, as it lies near the zone of maximum frequency of aurora, and auroral photography was one of the most important objects of the expedition Extensive studies were also made in meteorology, including upper air investigation, atmospheric electricity and terrestrial magnetism. The expedition occupied a site very near to that of the Canadian and British expedition during the first International Polar Year of 1882–83, and thus gave an opportunity for obtaining valuable determinations of secular change of the magnetic elements. Mr. Stagg will also describe some of the practical difficulties and interesting or unusual experiences which the expedition met with. As the lecture this year is of unusual interest, the Council has obtained the use of the hall of the Royal Geographical Society, Kensington Gore. An additional meeting of the Royal Meteorological Society will be held on March 28, at 5.30 p.m., at 49 Cromwell Road, South Kensington, when Prof. W. Schmidt, Director of the Central Meteorological Institute, Vienna, will deliver a lecture on micro-climatological work in Austria.

Announcements

Dr Harlow Shapley, director of Harvard College Observatory and Paine professor of astronomy at Harvard University, will deliver the George Darwin lecture for 1934 at the ordinary meeting of the Royal Astronomical Society on May 11, taking as his subject "Some Structural Features of the Metagalaxy"

At the annual general meeting of the Society of Public Analysts held on March 2, the following officers were elected for the year 1934 —*President*, Mr. John Evans ; *Vice-Presidents*, Messrs. L. Eynon, S. E. Melling, A More, W H Roberts ; *Honorary Treasurer*, Mr. E B Hughes ; *Honorary Secretary*, Mr G Roche Lynch.

At the annual general meeting of the Geological Society of London on February 16, the following officers were elected *President*, Mr J F N Green ; *Vice-Presidents*, Prof P. G H. Boswell, Prof. W. S. Boulton, Sir Thomas Holland and Mr. W Campbell Smith ; *Secretaries*, Prof W T Gordon and Dr. L Hawkes ; *Foreign Secretary*, Sir Arthur Smith Woodward, *Treasurer*, Mr. F N. Ashcroft.

A Conference on "Modern Changes in the Treatment of Light Soils" has been arranged to be held at Rothamsted Experimental Station on March 20, at 11 30 Further information can be obtained from the Secretary, Rothamsted Experimental Station, Harpenden

The Faraday Society has arranged a general discussion on "The Determination and Interpretation of Dipole Moments" to be held at Exeter College, Oxford, on April 12–14, under the presidency of Dr N V Sidgwick. The discussion, which will be introduced by Prof. P. Debye (Leipzig), will be divided into two parts, namely, determination and interpretation Among the foreign visitors who have promised papers are. Dr. A E van Arkel (Eindhoven), Dr. J. L. Snoek (Eindhoven), Dr. E Bretscher (Zurich), Prof. P. Girard (Paris), Dr O Hassel (Oslo), Prof. F Horst Muller (Leipzig), Prof. W H. Rodebush (Illinois), Prof. C P. Smyth (Princeton), and Prof. J. W. Williams (Wisconsin) Further information can be obtained from the Secretary, Faraday Society, 13 South Square, Gray's Inn, London, W C.1.

Applications are invited for the following appointments, on or before the dates mentioned :—Temporary civil engineering assistants for the London County Council—The Chief Engineer (D), County Hall, Westminster Bridge, S.E.1 (March 20). A head of the Department of Mathematics and Physics at the Municipal Technical College, Halifax—The Education Officer, Education Offices, West House, Halifax (March 23). Borough electrical engineer and manager, County Borough of Halifax—Town Clerk, Town Hall, Halifax (March 24). A demonstrator in inorganic and physical chemistry, Bedford College for Women —Secretary (April 21). A head of the Department of Building at Heriot-Watt College, Edinburgh—The Principal (April 23). A lecturer in chemistry, University of Reading—Registrar (May 7).

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Transmutation Effects observed with Heavy Hydrogen

WE have been making some experiments in which diplons have been used to bombard preparations such as ammonium chloride (NH_4Cl), ammonium sulphate ($(NH_4)_2SO_4$) *and orthophosphoric acid* (H_3PO_4), *in* which the hydrogen has been displaced in large part by diplogen. When these D compounds are bombarded by an intense beam of protons, no large differences are observed between them and the ordinary hydrogen compounds. When, however, the ions of heavy hydrogen are used, there *is an enormous emission of fast protons* detectable even at energies of 20,000 volts. At 100,000 volts the effects are too large to be followed by our amplifier and oscillograph. The proton group has a definite range of 14.3 cm., corresponding to an energy of emission of 3 million volts. In addition to this, we have observed a short range group of singly charged particles of range about 1.6 cm., in number equal to that of the 14 cm. group. Other weak groups of particles are observed with the different preparations, but so far we have been unable to assign these definitely to primary reactions between diplons.

In addition to the two proton groups, a large number of neutrons has been observed. The maximum energy of these neutrons appears to be about 3 million volts. Rough estimates of the number of neutrons produced suggest that the reaction which produces them is less frequent than that which produces the protons.

While it is too early to draw definite conclusions, we are inclined to interpret the results in the following way. It seems to us suggestive that the diplon does not appear to be broken up by either α-particles or by proton bombardment for energies up to 300,000 volts. It therefore seems very unlikely that the diplon will break up merely in a much less energetic collision with another diplon. It seems more probable that the diplons unite to form a new helium nucleus of mass 4.0272 and 2 charges. This nucleus apparently finds it difficult to get rid of its large surplus energy above that of an ordinary He nucleus of mass 4.0022, but breaks up into two components. One possibility is that it breaks up according to the reaction

$$D_1^2 + D_1^2 \longrightarrow H_1^3 + H_1^1$$

The proton in this case has the range of 14 cm. while the range of 1.6 cm. observed agrees well with that to be expected *from momentum relations for an* H_1^3 particle. The mass of this new hydrogen isotope calculated from mass and energy changes is 3.0151.

Another possible reaction is

$$D_1^2 + D_1^2 \longrightarrow He_2^3 + n_0^1$$

leading to the production of a helium isotope of mass 3 and a neutron. In a previous paper we suggested that a helium isotope of mass 3 is produced as a result of the transmutation of Li^6 under proton bombardment into two doubly charged particles. If this last reaction be correct, the mass of He_2^3 is 3.0165, and using this mass and Chadwick's mass for the neutron, the energy of the neutron comes out to be about 3 million volts. From momentum relations the recoiling He_2^3 particle should have a range of about 5 mm. Owing to many disturbing factors, it is difficult to observe and record particles of such short range, but experiments are in progress to test whether such a group can be detected. While the nuclei of H_1^3 and He_2^3 appear to be stable for the short time required for their detection, the question of their permanence requires further consideration.

Magneto-Caloric Effect in Supraconducting Tin

IN connexion with experiments on persistent currents in spheres, and in continuation of previous work on the energy content of supraconductors[1], measurements were carried out on the adiabatic magnetisation and demagnetisation of supraconducting tin.

We used a cylinder of 2 cm. diameter, 5.5 cm. long, with a phosphor-bronze resistance thermometer which was calibrated both with and without a field. The experiments were carried out in the temperature range 2.5°–4.0° K., and both longitudinal and transverse fields were used. The field strength was always considerably higher than the magnetic threshold values of tin.

We observed a cooling effect on magnetisation and a heating effect on demagnetisation. The heating was always greater than the corresponding cooling, as in both cases, when the field was above the threshold value, an additional heating due to eddy currents was produced. Measurements were mainly carried out on the cooling effect, which was found to increase from zero at the normal transition point (3.7° K.) to the lowest temperatures reached. The effect appeared to be the same for longitudinal and transverse fields within the limits of experimental error.

The cooling observed at the various initial temperature indicated was 0.05° at 3.3° K., 0.11° at 3.0° K., 0.21° at 2.7° K., 0.33° at 2.5° K. Still greater cooling could be obtained by using a magnetic field exactly equal to the magnetic threshold value corresponding to that temperature, as this would eliminate the heating effect of eddy currents.

The theoretical discussion of these results and their connexion with recent calculations by C. J. Gorter and others may be postponed until further experimental material is available.

Experiments are being carried out to investigate this cooling effect at lower temperatures and with different substances. It will perhaps be possible to use the adiabatic magnetisation of supraconductors as a simple method (as the fields necessary are small) of producing very low temperatures.

Kinetics of Photosynthesis and Allied Processes

THE photosynthetic process in the living plant consists of two separate reactions, namely, the primary photosynthetic reaction which has no temperature coefficient, and the dark or Blackman reaction which restores the conditions disturbed by the primary reaction and has a temperature coefficient The velocity of the primary reaction is proportional to the concentration of the chlorophyll on the irradiated surface, the intensity of light and the concentration of the hydrated carbon dioxide If these factors be denoted by a, I and P, respectively, the initial velocity will be expressed by k_1aIP, and the velocity at time t will be $k_1IP(a - x)$ The dark reaction is known to be unimolecular, and its velocity at time t will be $k_2xe^{-Q/RT}$. It is obvious that a photostationary state will be established when the velocities of the primary and Blackman reactions become equal, and if this state be established at time t, then the observed rate of photosynthesis will be given by

$$y = k_1IP(a - x) = k_2xe^{-Q/RT} \qquad (1)$$

Dividing by k_1IPx we have

$$\frac{y}{k_1IPx} = \frac{a-x}{x} = \frac{k_2}{k_1IP}e^{-Q/RT}$$

But $k_1IPx = k_1IPa - y$, where k_1IPa is the initial rate of photosynthesis, and for any one set of conditions is a constant, and if this be denoted by K we have

$$\log\frac{y}{K-y} = \log\frac{k_2}{k_1IP} - \frac{Q^1}{T}, \qquad (2)$$

where $Q^1 = Q/2\ 303\ R$

This formula expresses with great accuracy Emerson's four series of observations of the variation with temperature in the rate of photosynthesis with *Chlorella*[1] The value of K, as indicated by the formula, decreases with the chlorophyll concentration, and the four values of Q are 30,105, 29,309, 29,959, 29,905 calories, respectively, with a mean value of 29,819 calories

The formula also explains the fact, first discovered by Blackman and more recently observed by Warburg[2], that the temperature coefficient becomes unity when the intensity of light is small

By the elimination of x from (1) we obtain

$$y = \frac{k_1IP\,a\,k_2e^{-Q/RT}}{k_1IP + k_2e^{-Q/RT}} \qquad (3)$$

from which may be derived

$$\frac{I}{y} = \frac{1}{k_1aP} + \frac{I}{ak_2e^{-Q/RT}} \text{ and } \frac{P}{y} = \frac{1}{k_1aI} + \frac{P}{ak_2e^{-Q/RT}} \qquad (4)$$

These equations indicate linear relations between I/y and I, and between P/y and P, when the temperature is constant Warburg's observations[2] of the relations between the rate of photosynthesis and the intensity of light and the hydrated CO_2 concentration, respectively, at constant temperature are expressed by the above linear equations.

Let the case be postulated of heterogeneous catalysis in which the primary catalytic reaction is effected by the de-activation of the catalyst, and the de-activated catalyst is re-activated by a thermal reaction. If a be the initial concentration of the active catalyst, c the concentration of the catalyte, and d the concentration of the substance which re-activates the catalyst, then, if c and d be large and sensibly constant, equation (2) becomes

$$\log\frac{y}{K-y} = \log\frac{k_2d}{k_1c} - \frac{Q^1}{T},$$

where $K = k_1ac$ and y is the observed rate of catalysis. Equation (3) now becomes

$$y = \frac{k_1ack_2de^{-Q/RT}}{k_1ac + k_2de^{-Q/RT}} \qquad (5)$$

whence we have

$$\frac{c}{y} = \frac{1}{k_1a} + \frac{c}{k_2de^{-Q/RT}}$$

which indicates a linear relation between c/y and c when d and T are constant. Under these conditions, equation (5) may be written in the form

$$y = \frac{k^1ac}{c + K_m}$$

which is the well-known Michaelis equation for enzyme action when a and c are the concentrations of enzyme and substrate, respectively The wide applicability of the Michaelis equation and the close analogy between it and the equations expressing the rate of photosynthesis suggest that enzyme action is also a cyclic process, in which the primary catalytic reaction is effected by the de-activation of the enzyme, and the de-activated enzyme is re activated in a thermal reaction, possibly by the co-enzyme.

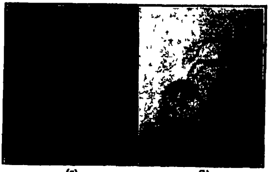
Formation of Vortex Rings from a Liquid Drop

A DROP of liquid heavier than water, for example blue or red ink, submerged quietly into still water, encounters the resistance of the medium and becomes flatter in its form in the course of its descending motion The central part of the disc thus formed soon disappears, and consequently a ring form results.



(a) (b)

FIG. 1.

This is a very slowly whirling vortex ring. As it proceeds, the radius of the ring is augmented, and it begins to disintegrate into several minor vortex rings Each of the secondary vortex rings proceeds in the same manner as the primary one, and disintegrates as well. The process of disintegration may be continued so far as the material remains ample.

This phenomenon has been described by Fr Ahlborn and shown diagrammatically[1]. I also studied this process of disintegration a few years ago, and several photographs were taken Those photographs were not published, and the matter has been forgotten. Ahlborn's description is, however, diagrammatic and not photographic · those photographs of mine, I think, might have some scientific interest. Two of them are reproduced here (Fig 1) (*a*) is one of the most beautiful examples, and represents the first disintegration stage and the beginning of the second disintegration (*b*) shows a further developed stage, but not a continuation of (*a*).

Scattering of Hard Gamma Rays by Lead, and the Annihilation of Positive Electrons

THE following experiment was carried out to make a further test of the hypothesis, proposed by Blackett and Occhialini, that the 'nuclear' scattering of hard γ-rays by heavy elements is due to the annihilation of positive electrons produced by the γ-rays[1]. γ-rays from an emanation tube were used, the source being placed at *S* (Fig 1). Observations were made on the ionisation produced in the chamber *I* due to the introduction of a thin lead foil (0 1 mm) into the position *BB'*, first, *with* an aluminium sheet (3 mm thick) at *AA'*, secondly *without* the aluminium sheet According to the above hypothesis, the ionisation should be greater in the first case, because the positive electrons which are produced in the lead foil and escape from it in the forward direction, are stopped in the aluminium sheet In the second case they are practically lost from the neighbourhood of the ionisation chamber, and therefore also their annihilation radiation. Apart from this, the only difference between the two cases is that, in the first, the lead foil absorbs some of the radiation scattered by the aluminium This tends to make its effect smaller than in the second case, and is therefore in the *opposite* direction to the above positive electron effect. Quantitatively, the absorption effect is, however, quite small, being only 2 per cent of the total effect of the lead foil.

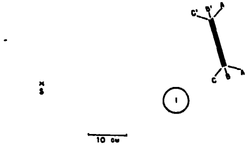

FIG 1

The results of several observations showed that the effect of the lead foil was greater when the aluminium sheet was present than when it was away, the difference being 25±3 per cent. The result provides direct evidence for the positive electron hypothesis. Quantitatively it is difficult to say whether the fraction 25 per cent is consistent with the supposition that *all* the 'nuclear' radiation from lead is due to the agency of positive electrons Two factors detract from a 100 per cent effect In the first place, a certain fraction of the positive electrons produced in the foil will not be able to escape from it in the forward direction, owing to insufficient range and to scattering in the foil Secondly, the wax sheet placed at *CC'* (which absorbs in all cases the positive electrons escaping backwards from the foil) is also a source of positive electrons, and the stopping of these by the lead foil further reduces the effective number which escapes from it

Accurate analysis is difficult, and to find, by this method, if some of the 'nuclear' radiation from lead consists of other radiation than that associated with positive electrons, observations with different thicknesses of foil and different degrees of filtering must be made The above observations were made with 1 cm lead filter in the path of the scattered rays. This was sufficient to absorb the Compton radiation, the angle of scattering being about 140°

Jan 22

[1] Since the present results were obtained, papers by Joliot and Thibaud (*Comptes rendus*, Dec 18, 1933) have appeared, which also report direct evidence for the annihilation of positive electrons, a magnetic field being used to deflect positive electrons so as to be stopped close to an ionisation chamber

Determination of Dipole Moments in Solution

SUBSTANCES the molecules of which contain a large permanent dipole give a marked decrease in the measured values of the molecular polarisation P_2 in solution as the concentration of the solution increases This effect has been ascribed to dipole association , it appears to be much too large to be due to association in the chemical sense of the term since, for example, nitrobenzene, which from many of its physical properties would be classed as a nearly normal liquid, shows a considerable fall in P_2 in benzene over the concentration range 0 5–2 per cent.

If P_2 is plotted against the volume polarisability $(\epsilon - 1)/(\epsilon + 2)$ for solutions of benzonitrile, nitrobenzene and chlorobenzene in a number of non-polar solvents, the points for each substance all lie near a straight line through the entire range of solutions to the pure liquid (Fig 1) The values of ∞P_2 found by Horst Muller for chlorobenzene and those recently given by Jenkins for nitrobenzene all lie close to the appropriate curve

This regularity appears to apply only to solutions in solvents with small or zero moments Thus solutions of benzonitrile in chlorobenzene measured by me give points which lie well below the line in Fig 1 Highly associated liquids, for example alcohols, may also be expected to deviate from the linear law

A crude picture of the phenomenon underlying the relationship shown in Fig 1 may perhaps be drawn as follows. The permanent dipole of a molecule in a solution may be regarded as surrounded by an 'atmosphere' of dipoles of opposite sign produced partly by induction in the polarisable solvent molecules and partly by orientation of adjacent permanent dipoles The measured polarisation therefore appears to be less than the true value The correction for the opposing atmosphere of dipoles should be a function of the volume polarisability of the solution, and the true value of P_2 should be obtained by extrapolating the curve to $(\epsilon - 1)/(\epsilon + 2) = 0$. It is clear from the large slopes of the curves for benzonitrile and nitrobenzene that the value for $_\infty P_2$ in any solvent will be lower than the extrapolated value since even for hexane $(\epsilon - 1)/(\epsilon + 2) = 0·228$

The other end of the curve also appears to be of interest When $(\epsilon - 1)/(\epsilon + 2)$ becomes unity

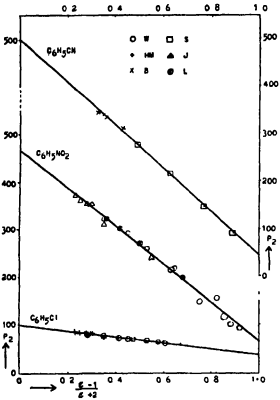

FIG 1 Relation of volume polarisability to molecular polarisation

HM Horst Müller, *Phys Z*, 33, 732, 1932
B Bergmann *et al*, *Z physikal Chem*, B, 10, 397, 1930
S · Sugden, unpublished data
J Jenkins, NATURE, 133, 106, Jan 20, 1934
L Lange, *Z phys*, 33, 169, 1925

$(\epsilon = \infty)$ the atmosphere of dipoles should neutralise the permanent dipole and only the distortion terms $P_A + P_E$ should be effective. If the curve is linear, its slope should then give $P\mu$, if it has a more complicated form, then the difference between the extrapolated values of P_2 for zero and unit volume polarisability should give $P\mu$. From the data in Fig 1, the best line through the observed points (calculated by the method of zero sum) gives the following values of μ in the usual units. benzonitrile 4·7, nitrobenzene 4·4, chlorobenzene 1·7 In benzene solution the first two substances give lower moments, 3·9 and 4·1 respectively, whilst chlorobenzene gives 1·52.

There are no data available in the literature for the dipole moments of these substances in the vapour state. Mr L G. Groves and I have recently measured the dielectric constants of the vapours of these and other substances with a high dipole moment and find for benzonitrile $\mu = 4·3$, and for nitrobenzene, $\mu = 4·4$ These results are of a preliminary character and may be modified by further work, they seem, however, to confirm the view that dipole moments calculated from $_\infty P_2$ in a solvent may be seriously in error when the dipole moment is large.

Predissociation in the First Positive Group of Nitrogen

THE electronic level diagram of the normal N_2 molecule is shown in Fig 1. The horizontal full lines represent the different electronic levels, the dotted lines the dissociation states, known transitions between the different molecular levels are represented by vertical arrows, whereas the electronic levels are connected by brackets with the atomic states into which they dissociate. As the position of the singlet levels relatively to the triplet ones is still rather uncertain, the zero of the scale of volts has been put at the triplet level $A^3\Sigma$ The dissociation states of the different molecular levels have already been given by various workers, of whom especially J Kaplan must be named[1] By his observation of the predissociation in the $B^3\Pi$-level of the first positive group (transition $B^3\Pi \rightarrow A^3\Sigma$) at

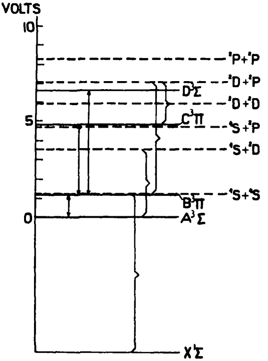

FIG 1.

$v' = 12$ and $v' = 20$, he was able to give strong evidence in favour of the diagram. Predissociation in the $C^3\Pi$-level was first observed by G. Herzberg[2] and studied in detail by D Coster, F. Brons and A v. d Ziel[3]. They interpreted this predissociation as due to the $^2D + {}^2D$ dissociation state, as was also done by Kaplan.

I am now able to bring forward new and strong evidence in favour of the diagram given above from a detailed investigation of the 12 → 8 transition of the first positive group ($B^3\Pi \rightarrow A^3\Sigma$) in which according to Kaplan the predissociation should occur. In this investigation, the work done by Naudé[4] on the $5 \rightarrow 2$ and $6 \rightarrow 3$ transitions of the same band system was of great value. Naudé has pointed out that the structure of the first positive group agrees with a $^3\Pi \rightarrow {}^3\Sigma$ transition. Twenty-seven branches are to be expected, nine strong branches and eighteen weaker branches. If the $B^3\Pi$ state were in Hund's case *b*, only the nine strong branches should occur. But the $B^3\Pi$ state is in case *a* for the lower J values and proceeds to case *b* for higher J values. A rotational analysis of the $12 \rightarrow 8$ band showed that the band lines suddenly become much less intense. This happens at $J = 32$ for the $^3\Pi_2$ level, $J = 33$ for $^3\Pi_1$ and $J = 34$ for $^3\Pi_0$, and in the R and P branches at the same place as in the Q branches.

This cannot be explained by assuming that the state causing this predissociation is $^4S + {}^4S$. This level gives rise only to Σ-states. Σ-states are in Hund's coupling case *b*. For such high rotational levels we are certainly also for the Π-states nearly in case *b*. Each one of the three Σ-states forming a triplet perturbs only one of the Π triplet states. These Π-triplets are double because of the Λ-doubling; Σ-states are not. Therefore only one of these Λ-doubling components of the Π states should predissociate, whereas on the contrary I observed the predissociation in both the Λ-doubling components (P- and R- as well as Q-branches predissociate). We thus may conclude that the perturbing level in this case is certainly not $^4S + {}^4S$ but that it may be $^4S + {}^2D$, as was formerly assumed.

The 'Manatee' of St. Helena

In my paper "On the 'Manatee' of St. Helena"[1] I brought forward evidence that the so-called 'manatee' formerly found at St. Helena was a sea-lion, probably the Cape sea lion, *Arctocephalus antarcticus*, not a sea-cow, natural conditions at St. Helena being quite unsuitable for sea cows.

Sir Charles Harper, formerly Governor of St. Helena, to whom I sent a copy of my paper, has very kindly directed my attention to a passage in Dampier's "Voyages" (ed. by Masefield, publ. by Grant Richards, London, 1906), which has a very important bearing on this question.

Dampier, who visited St. Helena in June 1691, also mentions the 'manatee', stating: "I was also informed that they get Manatee or Sea Cows here, which seemed very strange to me. Therefore inquiring more strictly into the matter, I found the Santa Hellena Manatee to be, by their shapes, and manner of lying ashore on the Rocks, those Creatures called Sea-lyons; for the Manatee never come ashore, neither are they found near any rocky Shores, as this Island is, there being no feeding for them in such places. Besides, in this Island there is no River for them to drink at, tho' there is a small Brook runs into the Sea, out of the Valley by the Fort" (I, p. 526).

Dampier gives (I, p. 64–67) an excellent description of the manatees and their mode of life from his own observations in the West Indies, the Philippines and Australia. Thus he knows what he is speaking about. His direct statement concords with the result reached indirectly through my own observations. The evidence is accordingly now conclusive that the much discussed St. Helena 'manatee' is a sea-lion, and the conclusions in regard to former land connexions drawn from the existence of the 'manatee' at St. Helena are without foundation.

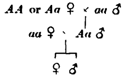
Possibility of Incomplete Sex Linkage in Mammals

In a paper shortly to be published, Koller and Darlington find that, in the first meiotic division of *Rattus norvegicus* males, one or two chiasmata are formed between the X- and Y chromosomes. If chiasma formation corresponds with the crossing-over of genes, it follows that where the chiasma lies between the locus of a gene and the region in which X- and Y chromosomes differ, such a gene will exhibit crossing over with sex. On the basis of the cytological observations, genes in a certain region of the chromosome should show about 5 per cent crossing-over with sex, in another about 45 per cent. These latter genes would behave in very nearly the same manner as autosomal genes. It thus follows that some genes regarded as autosomal may in reality be incompletely sex-linked. Such linkage would show up in a pedigree of the following type:



The progeny in the third generation would be in the proportions

55 *Aa* ♀ 45 *aa* ♀ 45 *Aa* ♂ 55 *aa* ♂

in a case involving 45 per cent crossing over. A glance through the literature shows that data must be available which would enable this hypothesis to be tested, but that they have not been published since the progeny of such matings are not usually classified for sex.

We wish to appeal to authors to give data in future communications which will enable the above hypothesis to be tested, and, where possible, to examine for partial sex linkage the data on which former publications have been based. It is most likely that such cases would be found in mammals, including man, where the Y chromosome is often fairly large as compared with the X-chromosomes, but they are perhaps also possible, *mutatis mutandis*, in birds and other groups.

The Floating Barnacle on the North Cornish Coast in the Summer of 1933

THE occurrence of the pelagic and planktonic floating barnacle, *Lepas fascicularis*, on the shore at New Train Bay, Trevone, near Padstow, Cornwall, in the summer of 1933, is an event sufficiently rare to be worthy of record along with other unusual marine events of that outstanding year

About fifty individuals (with capitula 13–32 mm in length) were taken alive on August 22 at about the time of high water (a m) at the beginning of a set of spring tides and within an hour or so of being stranded, some yielding living larvæ later. No others were found in the locality in the following week even after careful searching In water most of them floated freely by means of their spherical peduncular secretion (diameter 11–20 mm) containing gas-bubbles and vesicles, either singly, or in groups of two to five with their floating apparatus fused into one spherical mass (see Fig 1). Two small ones with capitula 21 mm and 22 mm were attached—along with the tropical barnacle, *L pectinata*—to floating fronds of *Fucus*, or to cinders, solely by means of a small flattened adherent expansion of the peduncle (thus confirming Ellis's original figure made in 1786), whereas others smaller and unattached (with capitula 14–20 mm) had well-developed floats Some of the larger individuals were attached to floating fronds of the seaweeds, *Fucus* and *Ascophyllum*, by extensions of the spherical float in such a way as to suggest that this organ may be adhesive and capable of expanding secondarily around a strange object, but simple experiments made under conditions normal for the species are required for further information Darwin[1] has shown that the larval peduncle is always attached to some floating object, around which the float is formed later, presumably—we suggest—when the animal develops a tendency to sink and perhaps in response to increased pressure.

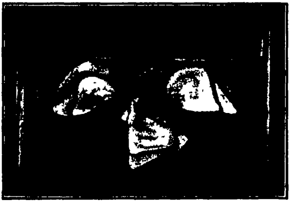

FIG. 1 A group of four barnacles, *L fascicularis*, attached by short stalks to the common float seen in the centre The group is photographed floating but held slightly submerged × about $\frac{7}{10}$ (Photo P Bond)

At various times the barnacles have been recorded as attached to a great variety of flotsam and jetsam, but the mode of attachment is rarely given. It would seem that a secondary attachment of the float would give a single animal greater mechanical efficiency in its feeding stroke, as no energy is required for or dissipated in maintaining a stable system; two animals on opposite sides of a free float with a body-beat synchronised would, however, appear to give efficiency. In this regard it may be that the special form of the keel plate is correlated with modified muscular requirements in a floating habit of life

This peculiar barnacle occurs in the open ocean and is recorded from all temperate and tropical waters[2], whence it is said to be blown ashore in various parts of the world by persistent winds. Damas[3], however, has shown that it is carried normally into the Norwegian seas from the Atlantic along with other Atlantic plankton at about mid summer In a similar way Schmidt followed the gradual extension of the planktonic *Salpa* from the North Atlantic into the North Sea in 1905[3] In some years, therefore, Atlantic plankton may be carried in the invading summer water, apparently independently of wind drift, into the North Sea, and there is evidence for a similar invasion of Atlantic water into the English Channel[4]. Whether the presence of the floating barnacle on the Cornish coast is an indication of an unusual offset of Atlantic water along the Cornish coast in the summer of 1933, or to a prevalent set of westerly winds, may perhaps be revealed later by hydrological observations.

Since 1786 only seven or eight records appear to have been made of the occurrence of *L. fascicularis* on the south coasts of England, and the same number for the west and north of Ireland[1,5,6] It has been found on the Northumberland coast on three occasions in the period between 1857 and 1894[7] In the latter cases the barnacles would appear to have followed the route of *Salpa* mentioned above from the Atlantic and have been afterwards blown ashore; they are not infrequently found in the North Sea[10]

L pectinata has been recorded only about five times since 1803 from the coasts of the British Isles[1,8,9]

It would seem that the interesting floating barnacle may often serve as a useful indicator of important physical events, and is therefore worthy of being more widely known

Travel of a Pulse of Stress in a Steel Wire

A BRIGHT drawn steel wire ½ in. diameter and 459 ft. long was arranged with one end lying in a solenoid which was excited with direct current. This end of the wire passed through a search coil placed near the central part of the solenoid, the search coil being connected through a valve set to an oscillograph The other end of the wire was firmly clamped When the clamped end was struck a sharp blow a pulse of stress was started and travelled along the wire with the speed of sound On reaching the search coil the changes of permeability of the wire due to the changes of stress gave rise to an E.M.F. which was recorded by the oscillograph. This pulse of stress was reflected from the end of the wire near the search coil and travelled back to the clamped end, was again reflected and once more reached the search coil end and again developed an E.M.F. which was recorded by the oscillograph. An inspection of the oscillogram (Fig. 1) shows that, in addition to the original pulse of stress which has travelled the full length of the wire before reaching the search coil, three successive reappearances of this pulse can be detected, each pulse being due to the reflection of the previous pulse at the clamped end of the wire.

The distance on the oscillogram between two successive records of the E.M.F. is a measure of the time taken for the pulse to travel twice the total length of the wire. The speed at which the pulse travels has been found in this way to be given by

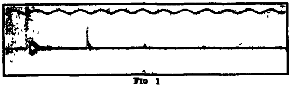

FIG. 1

$c = 5.04 \times 10^5$ cm. per second; or since $E = c^2\rho$, it follows that $E = 1.99 \times 10^{12}$ dynes per sq. cm., or, 29×10^6 lb. per sq. in.

The rate of decay of the amplitude of the pulse due to its passage to and fro along the wire is a measure of the damping.

One purpose of the investigation is to examine the influence of work hardening on this rate of decay, and thus to find out whether the effect can be used as a practical method for the detection of work hardening in the wires of wire ropes.

Chemistry of the Brown Algæ

OUR attention has been directed to a recent paper by Bergmann and Johnson[1] in which they describe the isolation of a sterol, m.p. 126-127°, from *Microciona Prolifera*, a deep red sponge from Long Island Sound. According to these authors, the sterol is a singly unsaturated compound of formula $C_{27}H_{46}O$, different in properties from either spongosterol isolated by Henze[2] or from clionasterol, described by Dorée[3].

We are at present engaged on a detailed survey of the marine brown algæ, and during the course of this work have isolated both from *Fucus vesiculosus* and *Pelvetia canaliculata* a sterol different in properties from the above mentioned sterols for which we propose the name 'fucosterol'.

Fucosterol melts at 124° (*acetate* m.p. 119°, *propionate* m.p. 104°) and gives analyses in good agreement with either a formula, $C_{29}H_{48}O$ or $C_{30}H_{50}O$. The presence of two ethenoid linkages in the molecule has been demonstrated by bromine absorption, perbenzoic acid titration and quantitative catalytic hydrogenation. A detailed account of the chemistry of this new sterol will be published elsewhere.

Cosmic Rays under 600 Metres of Water

IN October 1933, further work was done to investigate the hardest cosmic rays first found in the salt-mine of Stassfurt (Berlepschschacht der Preussischen Bergwerks- und Hutten A.-G.)[1,2]. The new observations were made in the same manner, and at the same levels, as in July, that is, under 500 m. and 1,000 m. of water; but this time they were extended to the second level (600 m. of water) and with two sets of double counter coincidence apparatuses operating simultaneously. They showed conclusively that these hardest cosmic rays penetrate also to 600 m. of water, as already expected from the 500 m. level measurements[1] and the earlier ionisation chamber observations[2]. From the July experiments[3] the apparent mass absorption coefficient $(\mu/\rho)_{H_2O}$ was deduced as being less than 5×10^{-5} cm.^{2} gm.$^{-1}$ if the penetrating power can be characterised by such a figure, which is of small value as compared with distinct specification of the absorbing screens penetrated.

The new measurements in the 500 m. and 600 m. levels confirm this coefficient as being less than 5×10^{-5} cm.^{2} gm.$^{-1}$ and show the upper limit to be 1.8×10^{-5} cm.^{2} gm.$^{-1}$. Full details of this, and of the other investigations such as the 'law of straight line', 'ω-effect' and directional distribution of these hardest rays, will be given elsewhere.

It is very interesting that Corlin[4], performing ionisation chamber observations in the iron ore mine Kiirunavaara near Kiruna (Northern Sweden) in a manner similar to that which I used in 1928 in Stassfurt, now deduces from his measurements at a depth of 52–86 m. of iron ore (215–430 m. of water) the existence of such hard rays with $(\mu/\rho)_{H_2O} = 1.1 \times 10^{-5}$ and 3×10^{-5} cm.^{2} gm.$^{-1}$.

A New Hard Component of the Cosmic Ultra-Radiation

PROF. KOLHÖRSTER has kindly directed my attention to a possible misunderstanding of the statement "a hitherto unknown component" in my communication entitled "A New Hard Component of the Cosmic Ultra-Radiation"[1]. This statement, which referred to the harder Kiirunavaara component, was not intended in any way to dispute Kolhörster's earlier discovery of a very hard radiation capable of penetrating more than 500 m. of water. I had, however, overlooked that Kolhörster has also mentioned[2] a small decrease of the ionisation even down to 700 m. of water found by him so early as 1928 in the Stassfurt mines; it is evident that the whole radiation found by him should not be identified with the softer Kiirunavaara component alone.

Research Items

Maize in China. In the annual report of the Librarian of Congress for 1933 (Washington, D.C.) Dr. Walter T. Swingle of the United States Department of Agriculture comments in the report of the Division of Orientalia on certain acquisitions in Chinese literature which refer to maize and other natural products. What would appear to be the earliest reference to maize in China is found in a work entitled *Liu ch'ing jih-cha* by T'ien I-hêng, who was born in 1524. The title of the work literally translated is "Preserved Green Daily [notation] Tablets", it being so called from the fact that it consisted of notes which had been scratched on the leaves of a bamboo grove by the author in his daily walks and meditations. Maize is here described in detail. It is called *yü mai* (Imperial grain) and is said to have come in through *Hsi fan*, literally the western barbarian region, a term which often was used to mean Tibet. Its old name is said to have been *fan mai*, literally barbarian wheat. It is thus clear that maize had been cultivated for some time before the publication of this work in 1573. Three further references to maize occur in Chinese literature between 1573 and 1590, of which at least one was copied from T'ien I-hêng's account. Wang Shih mou in 1587 gives a different name for it and says it was boiled and eaten. These accounts make it clear that within eighty years of the discovery of America by Columbus, maize had reached China. As the records are unanimous that it came from the west, Dr. Swingle suggests that it was not introduced by the Portuguese through Goa as is usually thought, but by the Arabs, who carried it from Spain to Mecca, whence Moslem travellers would have brought it to China through Central Asia. Tobacco, on the other hand, it would appear from a reference in another work, was not planted in China until the third decade of the seventeenth century.

Incubation of Mound-builders. Three papers in the *Victorian Naturalist* (50, Jan. 1934) discuss the habits of the mallee fowl or lowan (*Leipoa ocellata*), the most southern representative of the mound builders. Each mound is the work of a single female, and although in confinement as many as 29 eggs have been laid, in natural conditions 20 or fewer is the rule. The old ideas that the mounds were placed in water-tracks and that the eggs developed because of heat generated by the fermentation of leaves in the mound, must be given up; the mounds are dry and largely composed of loose soil, and development is due to sun heat. The purpose of such vegetation and sticks as are included in the mound is believed to be the prevention of the packing of the soil which would check access of heat and air. But the parent birds assist the process of incubation by scratching away and then replacing the sand on the top and about the rim of the mound, so that during the day the sun's rays may penetrate to the eggs, and that freshly warmed layers of sand may be piled upon the eggs to keep up the temperature during the night. The young when hatched are thus able to find their way to the surface through the loose soil, although when Mr. L. G. Chandler had the good fortune to see a chick emerge at the surface, it appeared at the spot where the old bird had been scratching. The writers differ in opinion about the future of the mallee fowl; one regards it as "doomed to extinction", because of interference with it and its habitat, another says "the extensive range of this most interesting species is my reason for stating that there is no need yet to say that it will soon be extinct".

Extent of the Retention of Ingested Aluminium. In a recent research report, one of a series on the hygienic aspects of aluminium cooking utensils issued by the Mellon Institute of Industrial Research, Pittsburgh, Pa., Messrs. Schwartze, Cox, Unangst, Murphy, and Wigman deal with the extent to which aluminium is stored in the tissues under conditions of a varied alimentary supply of soluble aluminium salts (*J. Amer. Med. Assoc.*, 101, 1933, p. 1722). Experiments were performed on guinea pigs, and the aluminium content of fresh tissues of animals receiving no added aluminium was found to be about 0.4 part per million. Feeding with large amounts of soluble aluminium salts produces a barely detectable deposition of aluminium—less than 0.5 per million in the soft tissues, and 0.5–1 part per million in the whole carcass. No ill effects were observed as a result of these feeding experiments, which in some cases were continued for 570 days, and it is concluded that no harmful effects are likely to occur from soluble aluminium naturally present in foods or introduced by utensils into a diet having a normal phosphorus content.

Plant Disease and Manurial Treatment. A definite correlation between the incidence of a plant disease and the type of manurial treatment applied is not of frequent occurrence, but it appears to be the case with a wilt, *Fusarium vasinfectum*, Atk., of the pigeon pea, *Cajanus indicus*, Spreng. This plant, commonly known as *rahar* in northern India, is included in the crop rotation grown on the permanent manurial plots at the agricultural farm at Pusa. W. McRae and F. J. F. Shaw have made a statistical study of the incidence of wilt on these and a number of other plots at the farm, and their results are published as Scientific Monograph No. 7, issued by the Imperial Council of Agricultural Research, Delhi. The disease was found to cause an average loss of 10 per cent of the plants, but neither the moisture content nor the hydrogen ion concentration of the soil was found to be the controlling factor. Manuring with superphosphate or with cattle manure, on the other hand, resulted in an increase in wilt, whereas green manuring (*Crotalaria juncea*) had the reverse effect and reduced the disease. A combination of superphosphate and green manure, however, brought about an increase in the number of plants affected. Several types resistant to this disease have been isolated, the factor for resistance showing no correlation with any of the morphological characters studied. An interesting feature in this breeding work was the discovery that resistance was lost in a field which had been under *rahar* for a number of years. Such a loss, however, was not transmitted to the next generation, only the soma of the plant being affected.

Estimation of Fungus Disease Intensity. A very interesting report of a "Symposium and Discussion on the Measurement of Disease Intensity" appears in

Part 2, vol 18 of the *Transactions of the British Mycological Society* (pp 174–186, Nov 1933) Three papers on the problems of measurement of intensity of particular diseases were delivered by Messrs A. Beaumont, R W Marsh and H B Bescoby, whilst a section on statistics was contributed by Dr A R Clapham Prof. W. B Brierley opened the discussion, and pointed out that there is usually no correlation between the intensity of disease in the plant and its extent in the crop Mr W Buddin outlined the difficulties of estimating disease intensity encountered by an advisory officer, and suggested that such estimation was only possible for purposes of research. Mr M H Moore showed how different methods of estimating disease intensity gave varying results of spraying trials

Minerals of Clay and Bauxite A statistical study of clay and bauxitic minerals has recently been published by S I Tomkeieff (*Min Mag* , 463 482 , 1933) which leads to a classification of these minerals on a purely chemical basis All the available analyses are plotted on two triangular diagrams and frequency curves are constructed for certain cardinal ratios, such as H_2O Al_2O_3 The suggestion is offered that among substances that have been claimed as minerals only a few can be regarded as definite species, and that the others are probably mixtures of the latter, or their hydration products, or colloids of variable composition The distinct crystalline minerals recognised are

pyrophyllite	H_2O	Al_2O_3	$4SiO_2$
kaolinite and its isomers	$2H_2O$	Al_2O_3	$2SiO_2$
diaspore	H_2O	Al_2O_3	
gibbsite .	$3H_2O$	Al_2O_3	

Probable species, of which, however, the statistical evidence is not clear, include termierite, anauxite and allophane

Study of Winds in the United States Supplement No 35 to the *Monthly Weather Review*, dated November 13, 1933, contains a great mass of statistical information of the kind that is apt to be very unpalatable to the ordinary student of meteorology, but is of value to aviators The work, which is by Loyd A Stevens, of the Aerological Division of the Washington Weather Bureau, is entitled "Upper-Air Wind Roses and Resultant Winds for the Eastern Section of the United States" The information was provided by the network of pilot balloon stations of the U S Weather Bureau, which has for some years given a fairly detailed picture of upper winds over the United States from day to day, but it has to be remembered that bad weather often makes soundings with balloons impracticable There are wind roses showing the frequency of winds from different directions and the average velocity from each direction, and also wind roses giving resultant winds, for heights of 750, 1,500, 3,000 and 4,000 metres, for each month and for the year The stations number fourteen, the most northerly being Sault Ste. Marie, Michigan, nearly in latitude 47° N , and the most southerly Key West, a little south of latitude 25° N. ; consequently they range from the westerlies of middle latitudes down to regions under the influence of the trade winds, and allow instructive comparisons to be made between the upper winds in the two major wind zones. Laborious statistical work of this kind is, of course, necessary before simple generalisations can be made with confidence about the general circulation of the atmosphere The labour of compilation in this case must have been particularly heavy, for the number of individual observations at some of the stations numbered more than 300 for a single month, even at 4,000 metres, where they are least numerous, and more than a hundred thousand observations were used altogether

The Ionisation of Cæsium Vapour by Light The ionisation of the cæsium atom by absorption of light is apparently one of the simplest photo ionisation processes Kunz (*Phil Mag* , Supplementary Number, Feb) has measured the amount of ionisation produced per unit of energy by light of different wave-lengths, using cæsium vapour at very low pressures (down to the vapour pressure of cæsium at 25 C) He finds that the probability of ionisation falls from the series limit at λ 3184 to a minimum at λ 2800 and rises again at shorter wave-lengths Braddick and Ditchburn have also published (*Proc Roy Soc* , A , Jan) their measurements of the absorption of light in cæsium vapour (already announced in a letter to NATURE of January 28, 1933) They find that the absorption falls to a minimum about λ 2800 and rises again at shorter wave lengths In order to investigate the short-wave rise, they made careful experiments at different vapour pressures of cæsium, and showed that the absorption varied linearly with vapour pressure throughout the wave length range. The absorption therefore appears to be attributable to the cæsium atom and not to molecules The absolute value of the absorption coefficient at the longer wave-lengths leads to a value for the photo-ionisation which agrees with experiment Taking these results in conjunction with the photo-ionisation experiments of Kunz and of former workers, it seems almost certain that the absorption is practically entirely due to the atomic photoelectric process and that the probability of this process increases in the shorter wave part of the ultra violet This result is in sharp antagonism to existing wave-mechanical calculations, which predict a monotonic fall in the probability on the short wave side of the series limit.

A New Theory of Valency A paper on " A Theory of Valency Based on Wave Mechanics and Band Spectra" by Profs R F Hunter and R Samuel was read at a joint meeting of the Chemical and Physical Societies of Aligarh Muslim University on February 21 It was shown that assumptions such as those of the co-ordinate link and the singlet linkage are physically inadmissible, and that Lowry's theory of the semipolar double bond, although physically more sound than Sidgwick's theory of co ordination, is impossible for energetic reasons It was also suggested that Sidgwick and Bayliss's later contention with regard to the expansion of the valency group of hydrogen, that a second quantum group is permissible on Pauli's principle (*J Chem Soc.*, 2027 , 1930) has no physical meaning, since wave mechanics have proved that it is impossible for electrons to enter the 2 *s* group while the 1 *s* group already possesses its maximum number of electrons , the curve of the potential energy of the third electron having no minimum and exhibiting only *repulsion* from the system Pauling's recent deductions with regard to the structure of carbon monoxide (*J Amer. Chem. Soc* , **54**, 988 , 1932) were held to be neither correct on the basis of his assumed value of 3 volts per covalency, nor from the electronic configuration of the terms and their dissociation

Boston Meeting of the American Association

THE ninety-third meeting of the American Association for the Advancement of Science was held in Boston on December 27–January 2. Harvard University and the Massachusetts Institute of Technology, with which other colleges in the metropolitan area co-operated, were sponsors and furnished rooms and other facilities for most of the sessions, which were thus admirably provided for. The Boston area is a centre of outstanding interest. Its educational and scientific features were placed at the disposal of visiting men of science and added in significant fashion to the effectiveness of the meeting

The local committee, with Dr A L Lowell, president of Harvard University as honorary chairman and Dr. K T Compton, president of the Massachusetts Institute of Technology as honorary vice-chairman, provided well for the needs of the occasion Despite the violent attack of historical New England winter on the first day, the programme was carried through successfully, due to the work of Prof S. C Prescott, chairman, and his associates The attendance numbered more than 3,200 scientific workers and the programme included 1,475 papers All fifteen sections of the Association were active and 34 of its affiliated societies held meetings In addition, the Academy Conference brought together official representatives of 19 State academies of science on Wednesday. These affiliated academies are active agencies in the advancement of science in their particular regions and meet annually with the Association to discuss problems involved in their co-operation and to agree on plans for future work. Most secretaries of sections and of affiliated societies remained for a study of organisation problems on the day following adjournment.

A noteworthy event, not on the official programme, was the dinner given to Dr J. McKeen Cattell On December 27, before the opening session, one hundred and thirty representative members and friends gathered to show their appreciation and pay respect to him for distinguished services to the Association The feature of the programme was an address by Prof. John Dewey on "The Supreme Intellectual Obligation".

The first formal session on December 27 was opened with the president, Prof H N. Russell, in the chair After customary addresses of welcome and response, the retiring president, Dr. John J. Abel, of Johns Hopkins University School of Medicine, addressed the audience on "Poisons and Disease". He discussed the chemical nature of disease as demonstrated adequately for certain diseases such as lock-jaw and diphtheria and strongly suggested in many other cases, hence the current trend towards the view that all diseases are due to poisons As he said, "Nature has not affixed a poison label to any particular substance or class of substances; the pharmacist does that." Dr. Abel further pointed out that many materials in the human body, and even the vitamins, though necessary and helpful in limited quantities, become poisons in larger doses. "I incline to the belief," he stated, "that no living cell exists whose contents or metabolites are not toxic to some other living cell."

The second Hector Maiben lecture, an endowed annual event, was given by Prof. W. M. Davis on the topic, "The Faith of Reverent Science". In this he set forth his concept of the views of reverent science and the hope of the future in the growing co-operation between thinkers in the fields of science and religion

On December 28 the general session was in charge of Sigma Xi, the Society for the Promotion of Research. The speaker, Prof Henry E Sigerist, addressed the Society and guests on the topic, "The Foundations of Human Anatomy in the Renaissance".

The Sedgwick memorial lecture, which was established by the Biological Department of the Massachusetts Institute of Technology, was given on December 29 by Dr Henry Fairfield Osborn. The magnificently illustrated lecture was an effective presentation of the subject "Aristogenesis, the Creative Principle in the Origin of Species"

On the same day, the Chemistry section and the North-Eastern Section of the American Chemical Society meeting jointly were addressed by Prof. Lafayette B Mendel on "The Challenge of Nutrition to the Chemist".

The general session on Agriculture and Engineering on December 29, arranged with co-operation also of the section on Social and Economic Sciences, portrayed vividly the trend of the times. The Secretary of Agriculture, the Hon. Henry Agard Wallace, spoke on "What can Engineering do for Agriculture?" His address was an appeal to engineers to forsake *laissez-faire* philosophy and to join in building up a co-operative State. He charged scientific workers with failure to weigh social consequences and challenged the widespread self-centred attitude of the past "To-day when the industrial nations of the world have skimmed most of the cream off the backward nations and the backward classes and when there are no longer any challenging geographical frontiers to be conquered, it becomes apparent", he said, "that we must learn to co-operate with each other instead of joining together in the exploitation of someone else"

On December 30 the American Academy of Arts and Sciences, meeting jointly with the Association, presented the Rumford medal for distinguished research in physics to Prof. Harlow Shapley, director of Harvard College Observatory and Paine professor of astronomy at Harvard, after which he addressed the meeting on "The Anatomy of a Disordered Universe". He elaborated the view that while the universe as a whole may be expanding, that part of it closest to man shows the opposite tendency.

A series of well-organised joint sessions and symposia formed an important feature of the programme Indeed the entire three-day programme of the section of Medical Sciences consisted of a series of such features Of particular general interest were the symposia on "The Chemical Revolution" by the sections of Chemistry and Social Sciences, on "National Economic Policy in its Relation to Our International Policy" by the section of Social and Economic Sciences, on "New England Dialect and Colonial Culture", by the section of Historical and Philological Sciences, on the "Development and Growth of the Nervous System", by the section of Zoological Sciences, on the "Positron" by the section of Physics, on "Engineering and the Farm Problem" by the sections of Engineering, Agriculture, and Social and Economic Sciences.

Four of the prominent affiliated societies, namely, the American Society of Naturalists, the American Society of Zoologists, the Botanical Society of America, and the Genetics Society of America, held a joint session on December 30 on the theme "Biology and Society". Prof W. M. Wheeler spoke on "Animal Societies", Prof E. A. Hooton on "Primitive Human Societies", and Prof F. H Hankins on "Development of Modern Social Organization". The American Society of Parasitologists and the section of Medical Sciences in joint session presented a programme on the "Typhus Group of Organisms", with demonstrations which aroused great interest. Other joint sessions of affiliated societies on plant physiology, ecology, entomology, phytopathology, parasitology and dental research would merit special comment if space permitted.

On December 30 the American Society of Naturalists celebrated its semi-centennial anniversary. Prof S H Gage was honorary chairman. After dinner the anniversary address was delivered by Prof E G Conklin on "Fifty Years of the American Society of Naturalists". Prof B E Livingston read his presidential address on "Environments".

The addresses of the retiring vice-presidents, given at various times, included the following: *Mathematics*, Prof. H H Mitchell, "Linear Groups and Finite Geometries", *Physics*, Dr D. L Webster, "Current Progress in X-Ray Physics", *Chemistry*, Dr Frank C Whitmore, "Some General Aspects of the Polymerization and Depolymerization of Olefins", *Astronomy*, Dr P W Merrill, "Invisible Star Light", *Geology and Geography*, Dr. William H Hobbs, "The Glaciers of Mountains and Continents", *Zoology*, Prof. A. S. Pearse, "Ecological Segregation"; *Botany*, Dr. H. L. Shantz, "Botanical Research", *Anthropology*, Dr C. H Danforth, "Genetics and Physical Anthropology", *Psychology*, Dr Walter S Hunter, "The Stimulus Control of Behavior during and after Learning", *Education*, Prof Stuart A. Courtis, "Differential Testing as a Method of Psychological Analysis", *Social and Economic Sciences*, Prof William F. Ogburn, "Recent Trends in Social Sciences", *Historical and Philological Sciences*, Dr. Waldo G Leland, "Recent Trends in the Humanities"; *Engineering*, Prof. Dugald C. Jackson, "The Origins of Engineering", *Medical Sciences*, Dr. C. R. Stockard, "Internal Secretions and Genetic Quality in Structural Development"; *Agriculture*, Prof. Joseph H. Gourley, "Plant Anatomy as a Tool in Agricultural Research".

The Science Exhibition, now a regular feature of the annual meeting, was, despite adverse economic conditions, the most successful yet undertaken. Colleges, private and Government research laboratories presented new and important work, both in pure and applied science, commercial exhibits of apparatus and products were extensive, among the displays of publications in science those of university presses were conspicuous, and the exhibits made by associations of teachers in biology, physics and mathematics attracted marked attention.

The Committee on the Place of Science in Education had arranged a special conference in which relations between teaching and the advancement of science were discussed from diverse points, and the results of new experiments in laboratories, science clubs and State academies reported.

The American Association prize of 1,000 dollars was awarded by the Committee on Awards to Dr Reuben L Kahn, bacteriologist of the University of Michigan, for his paper on "Tissue Reactions in Immunity: the Specific Reacting Capacities of Different Tissues of an Immunized Animal". By a method of measuring the degree of immunity acquired by different tissues, as shown by the author's investigations, warfare against germ diseases may be more successfully conducted.

The British Association was represented at the meeting by Prof. Arthur E Kennelly of Harvard and Prof F E Lloyd of McGill, the French Association by Prof W M Davis of Harvard, and the Bohemian Royal Society by Prof Henry B Ward of Illinois. Special delegates were also appointed by many American institutions.

The following officers were elected for the year 1934: *President*, E L Thorndike of Columbia University, *Council Members*, F K. Richtmyer of Cornell University, J C Merriam of Carnegie Institution, *Members of the Executive Committee*, K T Compton of the Massachusetts Institute of Technology, E G. Conklin of Princeton University; *Trustee of Science Service* for three years, to April 1937, J McKeen Cattell, *Vice Presidents of the Sections*, 1934: R D Carmichael, mathematics, H G Gale, physics, Joel H Hildebrand, chemistry, Frederick Slocum, astronomy, Jas B Macelwane, geology and geography, George L Streeter, zoological sciences, B O Dodge, botanical sciences, M J Herskovitz, anthropology, John E Anderson, psychology, Carl Snyden, social and economic sciences, Solon J Buck, historical and philological sciences, C. E Skinner, engineering, Cyrus C. Sturgis, medical sciences, J. G. Lipman, agriculture; Guy T Buswell, education, *Secretary of Section I*, John A McGeoch.

HENRY B WARD

Invention and Legislation

AT the sixth annual general meeting of the Television Society held at University College, London, on March 14, an address was given by the president, Sir Ambrose Fleming, on "Invention in Relation to National Welfare and its Legislative Control". Sir Ambrose referred to progress in television as an instance of one of the most interesting of the technical applications of science. It fulfils the same function with regard to the eye that radiotelephony does for the ear. It annihilates distance and enables us to see living and moving objects which would otherwise be invisible. In short, it enables us to be in two places at the same time. We are then led to consider the question how such an achievement can be made to contribute to national welfare, apart from its interest as a mere scientific novelty or amusement.

The great advances made in the use of short electric waves and closer scanning, and in photoelectric cells and cathode ray tubes, have made corresponding advances possible in television, and we can now transmit images of pictures, diagrams, or living persons and reproduce them on screens 3–4 ft. square, visible to large audiences at the receiving stations. We have in this ability a valuable means of education. Lectures and school lessons can be given by radio speech and illustrated by television diagrams or pictures Botany, astronomy, physiology and other sciences can thus be taught by visible diagrams A critic might say that this will diminish the demand for science teachers On the other hand, it would render possible the services of very able men and women of special knowledge and teaching power This particular application of television has scarcely yet been touched Where mere entertainment is desired, it will before long be possible to transmit special films of moving objects and, as it were, to bring the cinema into every home

These replacements which invention brings about force us into consideration of the question how far mechanical invention at the present day is responsible for the large scale unemployment which afflicts the world ? Different answers are given to this question Some hold that the replacement of manual power and skill by machine power which does ten or hundred times as much in the same time, is a fundamental cause of present distresses Others think that a primary reason is the deficient organisation in business, and that our methods of production have outrun our power of distribution Probably a still more basic cause is the enormous waste of world wealth and natural resources in wars and preparation for wars Humanity has not yet learnt how to live as one family or society and not as a collection of enemies and contesting rivals

Invention, however, requires guidance and control, and it is difficult to introduce new methods and ideas when any one branch of activity has become centralised in a few hands or petrified by becoming a Government monopoly This makes it necessary to point out how many disadvantages arise from erroneous or premature legislation intended to control invention This may be illustrated by the history of telegraphy, telephony, electric lighting and wireless telegraphy When after 1837 electric telegraphy became practicable by numerous inventions, public companies were formed to exploit it About 1866 or so, an opposition began to be raised to the growth of what was called another 'monopoly' The British Government of that day then passed Acts of Parliament in 1868–69 to enable it to buy out the telegraph companies and to place electric telegraphy under the control of the General Post Office

These Acts were, however, drawn with such skill that even ten years later when the telephone was invented and exchanges established, telephony was held to be subject to the above Acts Unfortunately, this decision rested merely on a judgment given in a court of first instance and was never confirmed by a higher court The General Post Office offered the telephone companies a licence for thirty years in exchange for a royalty of 10 per cent on their receipts. During those thirty years it took nearly a million and a half sterling from the telephone, but it blocked the way to advances in the art during all that time

The same story was repeated with electric incandescent domestic lighting In 1882 the Government passed an Act ironically termed an Act to "facilitate" it, but in fact it simply 'throttled' it for six years until an amending Act was carried in 1886 A similar fate attended wireless telegraphy In 1904 it was placed under the control of the Postmaster-General In 1926, when broadcasting of speech and music had become an important service, a charter committed it to the domination of the B B C and its small group of governors Television is now also in the control of the same power and the only chance given to prove its utility is at 11 p m., when few people have use for it.

Accordingly it is clear that premature legislation can easily cripple a nascent industry and bind it in bandages of red tape It is beyond defence that an invention which was not dreamt of at the date of a certain Act of Parliament should be controlled by that Act

In conclusion, Sir Ambrose Fleming advocated an extension of the period of patent protection, which at present is fourteen years in Great Britain, unless specially extended An invention is no use to the public until it becomes practically available or commercialised, and this generally requires time and great expenditure It is not possible to secure this without some reasonable prospect of return upon the capital, and in most cases a large part of the period of patent protection has elapsed before the point of commercial success is reached

University and Educational Intelligence

Cambridge —Dr R Stoneley, lecturer in applied mathematics in the University of Leeds, and Dr H M Taylor have been appointed University lecturers in mathematics

The Vice-Chancellor has appointed Dr A H Gardiner to the Frazer lectureship in social anthropology for the year 1934–35

Dr W H Thorpe and Dr W H Mills have been appointed to represent the University at the Eighth International Ornithological Congress to be held in Oxford on July 2 7

Prof E B Verney, professor of pharmacology at University College, London, has been appointed to the Sheild readership in pharmacology as from October 1

Edinburgh —The Senatus Academicus of the University has resolved that the honorary doctorate in laws be offered to the following, among others, for conferment at the graduation ceremonial to be held on June 28 Dr R Hutchison, physician to the London Hospital , Sir John Stirling-Maxwell, formerly chairman of the Forestry Commission and of the Royal Fine Art Commission for Scotland, chairman of the Ancient Monuments Board (Scotland) , Prof R Robinson, Waynflete professor of chemistry in the University of Oxford , Prof D'Arcy W Thompson, professor of natural history in the University of St Andrews

Applications, which must be received not later than April 15, are invited for the following scholarships awarded by the Council of the Institution of Electrical Engineers Inquiries for full particulars and nomination forms (specifically mentioning the name of the Scholarship) should be addressed to the Secretary of the Institution, Savoy Place, London, W C 2 Duddell scholarship (£150 per annum for 3 years), for candidates less than nineteen years of age on July 1 , Ferranti scholarship (£250 per annum for 2 years), for candidates less than twenty-six years of age on July 1 ; Swan memorial scholarship (£120 for 1 year), for candidates less than twenty-seven years of age on July 1 , Silvanus Thompson scholarship (£100 per annum and tuition fees, for 2 years), for works employees less than twenty-two years of age on July 1

Science News a Century Ago

University Tests

In the spring of 1834 there was, wrote Airy, who was then Plumian professor at Cambridge, "a furious discussion about the admission of Dissenters into the University." The repeal of the Corporation and Tests Acts in 1828 had removed many of the disabilities under which Dissenters laboured, but they were still unable to obtain degrees at either Oxford or Cambridge. Efforts to bring the matter before the Senate at Cambridge having failed, on March 21, 1834, Earl Grey, the Prime Minister, presented a petition in the House of Lords from certain members of the Senate praying for the abolition by legislative authority of "every religious test exacted from members of the University before they proceed to degrees, whether of bachelor, master or doctor, in arts, law and physic." In praying for the removal of these restrictions, the petition said, they were only asking for "a restitution of their ancient laws and laudable customs. These restrictions were imposed on the University in the reign of James I, most of them in a manner informal and unprecedented, and grievously against the wishes of many of the members of the Senate, during times of bitter party animosities. . . ." In a speech on the occasion, the Duke of Wellington remarked that the petition was nothing more than the petition of a dissatisfied minority though consisting of most respectable individuals, praying the House to interfere with the regulation of the University, in defiance of the immense majority of the Senate.

On March 24, the same petition was presented in the House of Commons by Mr. Spring Rice, but the petition was vigorously opposed by Mr. Goulburn, one of the members for the University of Cambridge. On April 17, Col. Williams moved that an address be forwarded to the King "requesting His Majesty to signify his pleasure to the Universities of Oxford and Cambridge respectively, that these bodies no longer act under the edicts or letters of James I, 1616." It was, however, determined to proceed by bill, and by 185 votes to 44 leave was given to bring in a bill to grant His Majesty's subjects generally the right of admission to the English universities, and to equal eligibility to degrees therein, notwithstanding their diversities of religious opinion, degrees in divinity alone excepted. The second reading of the bill was passed on June 20 by 321 votes to 174 and the third reading on July 28 by 164 votes to 75. When the bill was sent to the House of Lords, it was nevertheless rejected.

Among the most notable speeches in its favour was that of Lord Brougham, then Lord Chancellor. He supported the bill because it removed a practical grievance. "Surely," he said, "it was a great practical grievance, that instead of being admitted into one of the most illustrious, most ancient, and justly renowned seminaries of public learning, he should be forced to seek for education in another country. . . . Was it nothing that as a professional man he should not be admitted to the degree of a doctor of medicine, because he was not a member of the Church of England, and that to practise the faculty of medicine he must go to Berlin, or Paris, or Edinburgh or Glasgow? This was a law which savoured of oppression and was a practical grievance of great weight." He could not understand, he said, the consistency of those who gave the Dissenter admission to both branches of the legislature which must control the universities, and yet refused him admission to those very universities.

Discovery of the Tea Plant in India

Towards the end of the eighteenth century the difficulties which attended trading with China compelled the East India Co. to consider the possibility of growing various commodities, notably tea, in India. Sir Joseph Banks advised the Company that parts of Bengal would probably be suitable for the purpose. In 1826, the Commissioner in Assam had sent to Calcutta leaves of a shrub indigenous to that area which he believed to be a wild tea plant. This was not immediately accepted by the authorities, and it was not until the spring of 1834 that it was established that the genuine tea plant was native to India. Thereafter, the cultivation of tea became more and more extensive in India, the monopoly of the East India Co. was abolished, and India became ultimately the main tea growing country in the world.

In an article in Loudon's *Gardener's Magazine* of August, 1835, Dr. Wallich gives some details of the discovery made the year before. A commission, of which he was chairman, had been appointed to investigate the situation and reported "that we are enabled to announce that the tea shrub is, beyond all doubt, indigenous in Upper Assam. . . . We have no hesitation in declaring this discovery, which is due to the indefatigable researches of Captain Jenkins and Lieutenant Charlton, to be by far the most important and valuable that has ever been made in matters connected with the agricultural or commercial resources of this empire. We are perfectly confident that the tea plant which has been brought to light will be found capable, under proper management, of being cultivated with complete success for commercial purposes. . . . We are acquainted with the fact that the late ingenious Mr. David Scott sent down from Munipore specimens of the leaves of a shrub which he insisted was a real tea." By 1835 tea nurseries had been established in various parts of Northern India and the beginnings of the tea industry firmly established.

Improved Apparatus for Making Ship's Biscuits

In 1834, food scales in naval and merchant ships were unbalanced and rough. The subjoined statement by the Society of Arts relates to the award of a special premium during the session 1833–34, for an improved industrial process for the making of ship's biscuits:—"The large gold medal has been voted to Thomas R. Grant, of Weovil, near Portsmouth, for his improved apparatus for the manufacture of ship's biscuits. The apparatus was first erected at Weovil in 1832, under the immediate superintendence of Sir John Rennie. In Mr. Grant's apparatus the greater part of the labour is performed by steam power; the nine ovens in use are heated by one continuous fire-place, the flame of which is admitted by means of a register into each oven as soon as the previous charge has been withdrawn, and in five minutes brings it to a sufficient heat. The advantages claimed are superior economy and expedition, and better quality in the article. The present mode of making ship's biscuits involves, amongst the first operations, the mixing, by a man, of meal and water in due proportions; the kneading the dough for half an hour with his naked arms plunged up to the elbows, finishing by jumping into the dough and kneading with his feet A perfect and uniform mixture cannot result, shown later in some ship's biscuits being thin, some thick and scaly" (*Trans Soc. Arts*, 50, 7, 1834–35) The Society inspected an installation of this apparatus set up by a firm at Wapping

Societies and Academies

LONDON

Royal Society, March 8 J **Chadwick**, P M S **Blackett** and G **Occhialini** Some experiments on the production of positive electrons The emission of positive electrons has been observed under different experimental conditions (1) from a lead target exposed to the γ-rays of thorium active deposit (2) directly from a source of thorium active deposit, (3) from a lead target exposed to the radiations (γ-rays and neutrons) emitted by beryllium, boron, and fluorine when bombarded by polonium α-particles The measurements of the energies of the positrons ejected from lead by the thorium γ rays support the view that a positron and an electron are produced simultaneously by the interaction of a γ ray and an atom, and that the mass of the positron is the same as that of the electron The positron and electron are probably created in the electric field outside, rather than inside, the nucleus The observations show that when γ-rays of high frequency pass through an appreciable fraction (about one fifth for a γ-ray of $h\nu = 2{\cdot}6 \times 10^6$ volts) of the energy absorbed is used in this process of creating a positron and an electron G **Temple**: The quantum theory of the neutron This paper develops a theory of the neutron on the basis of the second order wave equation for the hydrogen atom, $(F^2 + m_0{}^2c^2)\psi = 0$, where F is Dirac's wave operator This equation possesses two types of solutions for which $\int_0^\infty \psi^2 r^2 dr$ is finite—the type H which yields the accepted wave functions of the hydrogen atom, and the type N which is here identified with the wave functions of the neutron Certain properties of the neutron are deduced from the form of the N solutions

Physical Society, Jan 19 E O. **Willoughby**: The measurement of the inductance of iron-cored chokes carrying direct current A method for measuring, by means of a reflecting dynamometer ammeter, the inductance of an iron-cored coil is described The coil is connected in series with a capacity and the ammeter, and then the junction of the inductance and capacity and the junction of the fixed and moving coils are connected to an A C. supply. For a constant applied voltage the deflection of the dynamometer ammeter is proportional to the square root of the reciprocal of the inductance This is also true when a direct current is superimposed on the alternating current flowing through the inductance Advantages of the method are the simplicity of the instruments and of the observations taken, the small value of the alternating current used and the independence of the method within wide limits of the frequency and wave-form of the supply. G. A. **Whipple**: A high-vacuum leak device The device described was designed for the control of pressure in the discharge tube of cold-cathode cathode ray oscillographs. It operates on a diffusion principle, and in this case permits of continuous variation of discharge tube pressures from 0·5 mm mercury to 'black' vacuum at 70 kilovolts. C. H. **Collie**: The use of charcoal in maintaining high vacua. Measurements have been made of the limiting pressures reached by charcoals and silica gels cooled with liquid air or liquid hydrogen when a small, constant stream of gas is admitted into the apparatus R A. **Fereday** On some measurements of magnetic susceptibilities at high temperatures Details are given of an electromagnet which has been specially built for carrying out measurements of small susceptibilities by a method, previously described by the author, in which specially designed pole-pieces are used. The method is applicable whether the pole-pieces are or are not saturated An apparatus for the determination of susceptibilities at high temperatures is described in detail. J. S. **Preston** and L. H. **McDermott**. The illumination-response characteristics of vacuum photoelectric cells of the Elster-Geitel type. The authors deal with the present status of the vacuum photocell as regards proportionality of photoelectric current to incident illumination, and give a series of observations which show that while excellent cells are obtainable, their employment for precise work without a previous test is unsafe A theory is developed which accounts for the observed results Attention is directed to the dependence of the illumination characteristic upon the colour of the light employed.

SUPPLEMENT.
Liquid Crystals. By Sir William Bragg, O.M., K.B E., F.R.S. 445

Scottish Chemical Industries

THAT it should become necessary to re-inspire Scotsmen with a belief in their own country seems strange indeed to those who dwell south of the Tweed, where the frequent demonstration of northerly patriotism is received with good-humoured tolerance and not a little pride. Scottish industry, however, is in different case from her highlands or her history, so that it has been thought desirable to enlist voluntary help in the promotion and development of all branches of industry in Scotland, and in that re-inspiration which will lead through confidence to ordered effort and material success Such a voluntary, non-political, non-trading organisation is the Scottish National Development Council, which was formed in 1931 under the auspices of the Convention of Royal Burghs and the Association of County Councils in Scotland. The Council, which enjoys the patronage of H R H the Prince of Wales and has as president the Earl of Elgin and Kincardine, undertook last year the task of constituting a number of expert technical committees to investigate and report on the present position and tendencies of industry in Scotland, on "the advantages enjoyed and the handicaps borne by Scotland in comparison with England and other competing countries, and to make recommendations for the exploitation of the former and the alleviation of the latter" It was considered important to examine the state of the chemical industry as soon as possible, and a survey of the position in that sphere of national activity has now been published*

The report opens with a significant phrase "The chemical industry," it states, "has never been of outstanding importance in Scotland—unless one views it in its widest scope, in which almost every industry is chemical " In the latter assertion lies justification for the insistence with which is advocated, in responsible scientific and industrial quarters, a wider recognition of the fundamental place of chemistry, of course with its correlated sciences, in preparation for industrial careers, particularly in preparation for the tasks which fall to the industrial and political directorate. In these columns the value of chemical science as an educational apparatus, in addition to its obvious claim to a prominent place among vocational subjects, has often been emphasised ; once again we assert that the study of chemistry need not always premise a career at the bench or in the factory, but that it provides a background of rational method and specific information which is of the greatest value in the ramifications of modern industrial and economic life. Such training could not but lead, for example, to a greater appreciation in financial circles of the material benefits to be derived from scientific research properly organised and adequately financed, and to a far more widespread determination, where power already exists, to recruit the 'shock brigades' of research in the van of progressive industry. The report remarks, in fact, that competition with regard to many chemicals is world-wide, and that their manufacture, dependent as this is upon research, highly-skilled control, and the use of large and modern plant, can be carried out only by those organisations which are capable of affording all those requirements.

---

* Report of the Committee on the Chemical Industry in Scotland. Scottish National Development Council Economic Series, No 9 (Glasgow, 39 Elmbank Crescent) 6d net.

Taxation and transport are other considerations of prime importance in industrial development. We are reminded that shrinkage of business caused by over-taxation, or by fear of over-taxation, expresses itself in general lack of confidence; this holds up enterprise on the part of existing firms and restrains new firms from setting foot in certain areas. The suggestion is made that districts which have advantages, such for example as reasonable rates, should advertise these and thus attract new ventures. It is surely in the end profitable for rating authorities to make only such demands as, in their informed judgment, will assist local industry and employment to expand and will attract new industries, with their corollaries of greater employment, more local trade, and a longer valuation list. This consideration appears especially pertinent in Scotland in view of the southward drift of industry towards large centres of population, although the existence of cheap rail or sea transport may prove a deciding factor. However, Scotland is well placed geographically for export markets, and the extension of motor transport is encouraging.

It is satisfactory that the report recognises that no useful purpose would be served by endeavouring to favour one portion of Great Britain at the expense of another in defiance of sound economic principles. "The considerations which govern the establishment and growth of an industry are, or should be, purely economic, and any departure from this standpoint is bound to be attended sooner or later with financial disaster." In other words, subsidies of whatever kind are dangerous expedients; the policy which is needed both locally and nationally is that which is based on accurate information, business acumen, courageous expenditure in the continuous acquisition of new knowledge, and the prompt application of such knowledge in overcoming the competition of rivals, whether at home or abroad.

Fermentation industries provide us with an example of potential development which will depend for its fruition on chemical research. The Scottish fermentation industry is, of course, severely handicapped by the extremely heavy excise duties on whisky and beer; moreover, public opinion and consequent legislation tend, and rightly so, to restrict its opportunities for expansion by discouraging the excessive consumption of alcoholic beverages. But alcohol is more than a beverage; it is a source of power and a substance from which numerous organic products may be derived. Therein lies its economic importance. As regards its use as a source of power the Government might well consider the suggestion that a minimum percentage of industrial alcohol should be incorporated in petrol; this action has indeed already been taken by a number of countries which have no indigenous supply of petroleum. So far as alcohol as a synthetic organic chemical is concerned, the report looks forward to the time when "the number of products made from ethyl alcohol and from other compounds obtained by fermentation may be almost as numerous as the progeny of coal tar". Let us hope that our fermentation industries and our agriculturists are fully alive to the implication.

Decline in the shale, textile, and shipbuilding industries in Scotland has affected the heavy chemical industry, which is primarily concerned with the production of raw materials for other manufactures, and tangible development is difficult to foresee. However, Scotland has had a large share of the explosives trade, gaining considerably by amalgamation of those interests. As a producer of leather she is in a relatively poor position, partly because most of the boots and shoes sold in Great Britain are made at Northampton or Leicester, and partly because she is largely dependent on outside sources for raw material. The patent leather industry is not carried on at all north of the Tweed, since in its early days lack of adequate sunlight for hardening the oil film militated against its establishment there; hence we are now dependent on Continental and American supplies The bleaching, dyeing, and calico-printing industry suffers from the Indian duties and boycott and from the growth of Japanese competition; "it seems unjust that Japanese goods should be admitted into any Empire markets on the same terms as British goods, while Japan imposes prohibitive tariffs against British goods in all territories under its control" The report on the rubber industry refers to the serious handicap of the tax on petrol and similar 'spirits' consumed in manufacturing operations, in the case of one Scottish concern a duty of 6*d*. per gallon adds £6,000 annually to manufacturing charges.

Iodine continues to be produced in Scotland, considerable quantities being still made from kelp at works in Falkirk and Clydebank, and it is interesting to note that there is one small works in England extracting iodine from kelp The amount obtained from this source is, of course, only a small proportion of the available supplies, most of which comes from Chile Again there is heavy competition from Japanese manufacturers who, not being members of the Iodine Convention, sell below Convention rates Other industries to which reference is made include those concerned with paints and varnishes, cement, chemical plant, barytes, coal, bitumen, wood and bone distillation, pharmaceutical products, food colours and flavourings, bichromate, firebricks, disinfectants, soap, etc

The pharmaceutical industry regards as necessary such regulations as have been imposed by legislation, but certain other industries complain of obsolete restrictions, while there is frequent reference to the need for cheap transport and amelioration of the burden of taxation It is suggested that Scottish manufacturers might exploit the goodwill which Scotland is said to enjoy in foreign countries by marking their goods "Made in Scotland". England, which owes so much to Scottish brains and Scottish character, will not begrudge any advantage which this delicate advertisement confers

Modern Thermodynamics

Modern Thermodynamics by the Methods of Willard Gibbs. By E. A. Guggenheim Pp xvi+206 (London: Methuen and Co, Ltd, 1933) 10*s* 6*d* net.

IT is an almost universal experience that thermodynamics is harder to understand than ordinary dynamics. For whatever reason this may be, the consequence is that in the textbooks it has not acquired the same standardised routine of development as has dynamics, but is treated from a great number of different angles As its title suggests, the present work uses the manner of Gibbs, but it takes advantage of the great advances that were consequent on Gibbs's work to bring the subject up to date The author has achieved a very high degree of success in his intention, and it is perhaps not too much to say that the book possesses not only the virtues, but also some of the defects of the great classic on which it is based. This criticism is not intended to belittle the book, which has much of the same classical character as its original; a cynic once said that a classic may be a great book, but that it is often one that is too dull to read, and though the saying is inappropriate here, still some readers may feel a faint echo of the sentiment, just as they would in reading its prototype. The resemblance of the two is in many ways very close, thus Gibbs never explains the elementary parts of the subject and nor does Guggenheim, though he is kinder than his predecessor in that he gives references for them to books which make entirely satisfactory introductions

Having got his basis, the author proceeds in the same leisurely and systematic manner as did Gibbs to develop all its consequences; everything is simple and straightforward, and the only trouble is the same as that which must have assailed many of Gibbs's contemporaries, the feeling 'It is all very nice, but what is a chemical potential anyhow?" In those days this was inevitable as no chemical data existed to illustrate the subject, but in view of the work of G N Lewis and others, the matter is very different now and it would have been quite possible to give detailed numerical examples to illustrate all parts of the subject. Granted that to do so would have rather diminished the resemblance of the book to its prototype, yet the departure would have been a material help, and it is surely no part of the tribute of reverence we should pay to a great work to insist that the difficulties under which it was written should be imitated

As to the details of contents, the book begins with a short account of foundations The author makes a very just comparison between thermodynamics and dynamics, in dynamics the beginner learns the subject starting with Newton's laws, but for more advanced work a new foundation is made with the help of Least Action. This is usually preferred by the expert, but would be useless for the beginner, and the present work is to be likened to the more advanced type in dynamics. There is no explanation of entropy, it is regarded as a primitive idea like temperature This seems an admirable plan, but it is incompletely worked out, since the consequence must be to degrade energy to some less primitive position, for otherwise there would be three primitives instead of the usual two However, nobody ever agrees about foundations, and the only generalisation about them that holds (and even this will command almost universal dissent) is that though they are things one cannot do without, the exact form of them is a quite unimportant matter of taste

In the second chapter the author develops all the general differential relations of the subject, and a most attractive feature is that everything is systematically done for all four forms of the thermodynamic potentials, instead of allowing one of the four, the internal energy, to have its usual but unmerited position of privilege After this, the author proceeds to build up the whole of chemical thermodynamics, starting with systems of a single component, and then treating of gaseous mixtures, and so arriving at his main subject of solutions These he classifies into ideal, semi-ideal and non-ideal, and the special discussion of the intermediate type will probably be found a most useful simplification of the subject Making a cross-classification in another chapter, he discusses solutions from the point of view of their diluteness Altogether, solutions are very fully treated, the original ideas of Gibbs being supplemented by the fruitful conceptions of fugacity, and of activity and osmotic coefficients, which have been brought to the fore by Lewis and others These conceptions have served to make the dry bones live, our only criticism of their discussion here is that the bones are discussed as they would be in a work on theoretical anatomy, rather than as in one on natural history

Then there are chapters on electro-chemistry (but not including thermo-electric phenomena), and on surface phases, this last includes not only the thermodynamics of surface tension, etc, but also the quite different subject of such surfaces as grease films on water, which were unknown in Gibbs's day There follows a very short chapter on radiation, which tells too little or too much, for it gives Stefan's law, but not that of Wien. The final chapter goes outside the field of classical thermodynamics and gives a short account of the so-called third law, and of chemical constants. The author adopts the necessary data from statistical theory, wisely avoiding much explanation, and illustrates the results by good short discussions of many of the substances for which the chemical constant is known; in this particularity he advantageously departs from the rather too abstract method of the purely thermodynamical part of the book

It will be seen from the above that the book is not to be regarded as an introduction to thermodynamics It will find its use partly by the mathematical student who wants everything set out in an orderly and systematic manner, and partly by the physical chemist who wishes to see how his more specialised ideas can be fitted into the general scheme Altogether, it will be found a most useful work of reference for the general theory of chemical thermodynamics. Richard Trevithick

Richard Trevithick · the Engineer and the Man. By H W. Dickinson and Arthur Titley (Trevithick Centenary Commemoration Memorial Volume) Pp. xvii + 290 + 18 plates (Cambridge: At the University Press, 1934) 10*s* 6*d* net

IN William Walker's well-known group of British men of science alive in 1807–8 there is no more romantic figure than that of Richard Trevithick, who at that time was struggling with the problems of steam transport by road, rail and river and was also endeavouring to bore the tunnel known as the Thames Archway beneath the Thames between Limehouse and Rotherhithe The latter was a project which Trevithick, with that buoyant optimism which was one of his characteristics, had undertaken, thinking "this will be making a thousand pounds very easey, and without any risque of a loss on my side" Entered upon without sufficient preparation and with inadequate appliances the scheme proved a failure, but Trevithick's position as the engineer of the concern had some share in making his name widely known and perhaps had some influence on Walker when choosing his portraits for the group of 1807–8. At any rate, we know to-day how well Trevithick deserved to be placed beside Watt and Telford, Brunel and Maudslay, Davy and Dalton

The outstanding feature of Trevithick's lifework was his application of the high-pressure steam engine In this direction he was a great pioneer and this at a time when the practices of Watt were looked upon by many as the acme of achievement Trevithick's early life was passed amidst the Cornish mines where Boulton and Watt's low-pressure engines working with steam at 2 or 3 pounds' pressure had saved many a mine from closing down Boulton and Watt, say the authors of this book, were "the greatest benefactors that Cornish mining has ever had" Where Trevithick got his revolutionary idea of making small compact engines without beams, air pumps and condensers, and circular wrought-iron boilers, using steam up to 50 or 100 pounds' pressure, we do not know, but he had already launched out in this direction before the patent of Boulton and Watt had expired

It would be a mistake to think of Trevithick as wholly absorbed by his engine work, for he was seldom content with only one iron in the fire and was easily lured aside from the main business of the moment Yet as can be seen from the chronology given by Messrs Dickinson and Titley in this admirable 'Life' of Trevithick, the high-pressure engine ran as a connecting thread through his whole career In 1797 he made models of stationary and locomotive engines, in 1798 he constructed his first high-pressure winding engines, in 1801 his first steam carriage and in 1802, with Vivian, took out his great patent A year later, in 1803, he made his second steam carriage together with some stationary engines for Wales, in 1804 he constructed the Penydaran rail locomotive, in 1805 the Newcastle locomotive, and these were followed in 1806 by his steam dredger and in 1808 by his locomotive *Catch me who can* Overtaken by sickness and bankruptcy he then returned to Cornwall, where during the years 1811–1814 he made high-pressure pumping engines, agricultural engines and engines for the Peruvian mines for which low-pressure condensing engines were unsuitable It was his work for the Peruvian mines which opened to him the prospects of wealth and led him in 1816 to sail for South America. That great adventure, of which we would know more, failed through causes beyond his control, and when eleven years later he returned home, his sole possessions were "the clothes he stood in, a gold watch, a drawing compass, a magnetic compass, and a pair of silver spurs" As always, however, he faced the situation quite undaunted, and to his later years belong those flashes of genius of which the authors write so sympathetically in the sixth and last chapter of their book

Of Trevithick's upbringing, his environment, his character and abilities, his generosity and want of prudence, his fertility of invention, his thoughtlessness in domestic affairs, his triumphs and his failures, each must read for himself He was no ordinary man and had some of the attributes of a genius and a hero. Born in Cornwall in 1771, he died in poverty at Dartford in 1833, and last year his centenary was commemorated in a worthy manner To that commemoration we owe the publication of this book The Commemoration Committee deciding to publish a memorial volume, Messrs Dickinson and Titley generously offered their partially completed work and it was accepted Funds, however, not being forthcoming in sufficient amount to pay for its printing, Messrs Babcock and Wilcox, Ltd undertook to bear the cost of publication as their special contribution to the Centenary Fund In these happy circumstances the book now makes its appearance in a style worthy of the publishers and at a price at which no one can cavil It is admirably illustrated and besides the chronology and the six chapters dealing with the various stages in Trevithick's career, there are appendices dealing with his memorials, his patents and his descendants It is certainly one of the best that we know of engineering biographies

The Werewolf

The Werewolf By Montague Summers Pp xiv + 307 + 8 plates (London Kegan Paul and Co, Ltd, 1933) 15s net

THERE are various ways of approaching the problem of the occult, as has been shown in the literature on witchcraft which has appeared in the last decade The fashion of a previous generation which regarded it as a mere superstition of the Dark Ages, happily, has passed away in favour of a more rational attitude such as that of the anthropologist, who seeks to relate the belief to the magical and religious practices of primitive peoples, as an accompaniment of a phase in man's development, or of the psychologist, who seeks to derive an explanation of magical phenomena from mental aberration

The belief in the werewolf, the 'man-wolf', who puts on an animal form and preys on his fellow men, which was current in medieval Europe and survived down to modern times, is thus regarded either as of a piece with the belief of primitive peoples in the possibility of 'shape-shifting' and, generally, as belonging to their attitude towards animals as in some way uncanny , or, alternatively, as based upon misinterpreted observations of perversions, such as necrophany and lycanthropy, or forms of hysteria and delusional insanity, to which the social and economic conditions of the Middle Ages rendered the populace especially prone.

Mr Summers confines his study of the werewolf to its occurrence in Europe, passing over in a brief reference the werelions, tigers, hyenas and leopards of primitive peoples. He also includes in this class the fox belief of China, strictly speaking, this is not a werewolf belief, but its contrary, for the Chinese fox spirit turns into a man or possesses a human being and not vice versa Mr Summers deliberately sets aside the evidence from primitive peoples and he rejects the anthropological point of view in favour of the theological, to which he regards anthropology as merely ancillary Hence the belief is treated from the angle of Catholic orthodoxy, and apart from chapters dealing with the records of cases of the werewolf in the various European countries, discussion is confined to the opinions and rulings on the subject of the werewolf of writers on witchcraft and magic in the Middle Ages and immediately succeeding centuries Mr Summers has an intimate and extensive knowledge of this literature, and his careful analysis and full quotation from the authorities provide a mass of information on this aspect of medieval thought, as well as a useful guide for the use of those who wish to pursue the subject further

The werewolf in theological argument was regarded as closely allied to the witch , both were believed to derive their powers from a pact with the devil. As the object of the change of form into a wolf was to prey on human beings and devour their flesh, the werewolf was also closely related to the vampire. Hence it is not surprising to find that the werewolf belief flourished in eastern Europe, the home of the vampire , and there both beliefs still survive. Russian peasants to-day think that Lenin for a time was a bear. Here they are in agreement with their forerunners, for in the sagas of northern Europe, the animal form assumed was the bear, and the prevalence of the belief is shown by the familiar expression 'bersork' It is well known that this peculiar relation with the bear still holds among the primitive tribes of northern Asia across to the Far East, where it takes the form of the bear cult, with which the writings of Sir James Frazer have made us familiar It is unnecessary to look further for an analogy upon which to base a suggested origin for the werewolf type of belief , but this Mr Summers would be precluded from admitting as relevant by his theological prepossessions

Medieval theologicians, not having the advantage of a Sir James Frazer to assist their speculations, were faced with the dilemma of either denying a fact accepted as such by the Church, or supporting an opinion dangerously like a heresy in attributing an act of creation to a power other than God Their subtle arguments and skilful evasion of the difficulty leave the reader to ponder the nice problem of the conflict between authority and scientific evidence, which Mr. Summers solves by whole-hearted acceptance of the former.

Short Reviews

Wundkompensation, Transplantation und Chimaren bei Pflanzen. Von Prof N P. Krenke. Übersetzt von Dr N. Busch Redigiert von Dr O Moritz. (Monographien aus dem Gesamtgebiet der Physiologie der Pflanzen und der Tiere, Band 29.) Pp. xvi+934. (Berlin · Julius Springer, 1933.) 89 80 gold marks

THIS extensive work first appeared in Russian in 1928 under the title "The Surgery of Plants" The German translation has been edited and brought up to date with the aid of the original author It is a thorough-going treatment of growth reactions following wounding and the phenomena connected with transplantation and grafting from a causal point of view Regeneration is considered from every aspect, including chromosome multiplication, hormones and the theory of mitogenetic rays. Many teratological phenomena find here a causal explanation A considerable amount of modern cytological and genetical work is brought to bear on these problems, and the early but often forgotten work of Darwin is extensively and aptly quoted.

A well-illustrated section of 240 pages deals with the formation and structure of chimæras, a field in which Prof Krenke has made extensive studies. The whole subject is treated in a way which will throw further light on their nature. The last section deals briefly with the introduction of foreign substances into plants and acquired immunity.

The extensive bibliography includes many Russian papers which might not otherwise be known in other countries. Notwithstanding the usefulness of this work, the price appears inordinately high even although two coloured plates of chimæral *Solanum* fruits are included

R R. G.

The Cult of the Goldfish. By T C Roughley. Pp xiii+146+29 plates (Sydney Angus and Robertson, Ltd ; London Australian Book Co., 1933) 6*s* net

MR. ROUGHLEY has written perhaps the best book on gold-fish culture that has yet been published It is a most useful volume, well produced and full of interest from beginning to end The author thoroughly understands his fish and shows how they will respond to considerate treatment Those who read these pages will never wish to keep a gold-fish in a bowl again, but they certainly will wish to keep a real aquarium and care for the fish in it , moreover, directions are given for making the aquarium or pond at home, which must appeal to many craftsmen

The varieties of gold-fish are numerous and new kinds are constantly appearing Breeding gold-fish is an exciting occupation and apparently not so very difficult if care be given to essentials The aquarium made, one is taught how to supply it with suitable plants The varieties of gold-fish are discussed and their food, also which animals may be put in with them to advantage and which should be avoided There are chapters on spawning and development, the garden pool, animal pests in ponds and diseases of gold-fish.

Not only are the life-histories of the food animals discussed, but also those of the diseases to which the fish are subject and of those animals which may be found in the pond Thus the mosquito is useful as the larvæ are a good food, pond beetles and dragonflies are harmful, the larvæ eating the young fishes The information given on the diseases which so often affect gold-fish is extremely interesting and full remedies are discussed

Virus Diseases of Plants By Dr John Grainger Pp viii+104+6 plates (London Oxford University Press, 1934) 6*s* net

OUR knowledge of the plant viruses has increased enormously in the last decade We have not yet, however, arrived at any definite conclusion as to the nature of this interesting group of pathogens In this book, the whole problem of virus diseases and their etiology is compressed into seventy-five pages, with, in addition, twenty-five pages of bibliography The first chapter is devoted to a very short account of the general subject. The second deals with the relation of the virus to its host plant—with special reference to some of the better known viruses It is not quite certain that the suggestions in the section on cytology, that a 1/12 in oil immersion lens is necessary for the examination of the *X*-bodies and that these bodies frequently disappear by the erosion of the protoplasmic stream, would meet with general acceptance among cytologists Chap. iii is devoted to the physical and chemical properties of the virus so far as these are known. The fourth chapter deals with the important problem of the insect transmission of the disease and gives some meagre notes on the treatment of insects under experimentation The chapter on the economic effects and the control of the disease is probably the most useful in the book It deals with methods for preventing the spread of the disease The classification and description of virus diseases is dealt with in chap vi

This book will be of use mainly as a general account of the plant virus problem

Celtic Ornament in the British Isles down to A D 700 By E T Leeds Pp xix+170+22 plates (Oxford Clarendon Press , London Oxford University Press, 1933) 12*s* 6*d* net

IN this study of Celtic ornament, Mr E T Leeds has elaborated a communication presented to the first International Congress of Pre- and Protohistoric Sciences in 1932 It is a survey of the subject as a whole from the earliest appearance of distinctively Celtic art after the coming of the early Iron Age peoples to Britain down to the beginning of Anglo-Saxon times The various types of characteristic motifs are traced in the finds from initiation to decay and their relations and distributions analysed Such detailed discussion was eminently desirable, as nothing of a similarly comprehensive nature had been attempted since Romilly Allen's work on Celtic art in pagan and Christian times of more than thirty years ago In the meantime, not only has the material which Allen had before him come to be more clearly understood, but also much new material has accrued, bringing with it a clearer appreciation of the problems which call for solution Mr Leeds's views on the renaissance of Celtic art after the Romano-British eclipse, especially when they differ from those of Mr T D Kendrick, will repay careful consideration

Neurological Effects of Syphilis Diagnosis and Treatment By Dr B Buckley Sharp (Oxford Medical Publications) Pp v+92 (London Oxford University Press, 1933) 7*s* 6*d* net

DR B BUCKLEY SHARP has provided us with a very interesting book on neurosyphilis , but it might very well have been larger There are several statements with which we are inclined to find fault To state categorically that "there are no clinical entities exclusively syphilitic" is a misstatement There is no better-defined clinical entity than general paralysis, which is in 100 per cent cases exclusively syphilitic Again, vascular lesions are present in certainly 80 per cent of neurosyphilitics

The author appears to be prejudiced in favour of including intracisternal salvarsanized serum in treatment, for he says he and Purves Stewart have never seen a return to a normal fluid without using this treatment This is not the experience of the majority. The section dealing with diathermy might well have been expanded, a large amount of work has been done on this form of treatment. A 2 gm dose of tryparsamide is just as satisfactory as 3 gm and much safer.

The Drinking Habits of Birds

By SETON GORDON

THE lover of birds who places a shallow dish of fresh water each morning beside the bird table and has the pleasure of seeing chaffinches, robins and other of his bird friends drink eagerly from it, may perhaps have wondered how young birds in the nest receive the moisture which is necessary to them, or how sea-birds drink

I do not think that the young of any British birds actually drink in the nest, they receive their moisture in the food which is brought them, and it is partly no doubt because they cannot drink that the parents are so careful to shield them from the direct rays of the sun before they are feathered It is not perhaps generally known that direct sunlight is fatal to young birds The gannet is one of the hardiest birds, yet I have known a young gannet succumb after being left unattended in the nest for the space of rather more than an hour while the strong August sun beat down upon its small, black, naked body Even the golden eagle, which leaves its eaglets unprotected to the snow-laden wind, builds its eyrie almost always where the nest faces north and thus is sheltered from the sun During a recent early summer, my wife and I watched almost daily for the space of a fortnight at an eagle's eyrie from a heather hide The eyrie was facing north-east, and the sun did not shine on it after eleven o'clock in the morning One morning after a very cold spell the sun shone strongly on the eyrie The morning had been dull and close, and when the sun, shortly after half past ten, suddenly emerged from one of the heavy clouds, its rays were brilliant and for once I felt comfortably warm in my hiding-place The mother eagle was standing at the edge of the eyrie, and when the sun appeared walked over to the eaglet (which was three weeks' old and covered with thick white down) and, standing between it and the sun, slightly opened her great wings to shelter it The sun increased in power, and gradually, in three distinct movements, she spread her wings to their fullest extent and stood quite motionless The beauty of that picture I shall long remember My peep-hole was not more than twelve feet from the nest, and every feather of the eagle was distinct, the great wing primaries drooping to the sides of the eyrie The sun gradually left the eyrie and when the nest was in shade the eagle folded her wings, walked to the edge of the eyrie and launched herself on the air with a sudden splendid gesture.

The young golden eagle is hatched early in May and does not take its first flight until mid-July. During all that time it never drinks, but depends for its moisture on the food brought to it—hares and grouse, rabbits, even stoats and squirrels But does the adult eagle drink ? Some observers believe that it never does so, but a stalker told me that he once came suddenly on a golden eagle bathing, if not actually drinking, in a clean pool of a hill burn, and in his words "when she had finished bathing herself she walked to the edge of the pool and shook out her feathers just like an old hen"

There may be quite a number of our land birds which do not habitually drink, and what of the great army of sea-birds that live their whole lives on the salt water ? Do they drink sea-water ? Or do they never drink ? I do not refer to the sea-gulls, which spend a part of their time on land, but to the vast armies of guillemots which crowd the rock stacks in summer as they incubate their eggs on arid sunbaked ledges, to the colonies of razorbills, cormorants and shags, to the storm-loving petrels and the gannets which fly tirelessly a hundred miles and more to catch a fish for the hungry family The only water which all these birds know is the salt water of the ocean Do they drink it or does their fishy food, saturated with moisture, supply them with liquid enough ? Even if they do not drink salt-water, they must have some means of dealing with their food, which is salt-impregnated, and would probably be fatal to a land bird All who know the great northern diver, the guillemot, the black guillemot and other divers of the sea must be familiar with the habit of all these birds of dipping the bill constantly into the water after a dive and also when swimming This is done whether the bird has caught a fish and swallowed it, or whether the dive has been unsuccessful, so that it cannot be to clean the bill The impression given superficially is that the bird is drinking, but I am rather inclined to believe that it is a habit, perhaps originally adopted when cleaning the bill It is interesting to note that when human inquirers approach a nesting place of a pair of black guillemots the birds swim rapidly backwards and forwards, calling shrilly and repeatedly dipping their bills in the water

There is one exception to this habit of bill-dipping among the divers of the sea The puffin does not dip the bill, although it is as assiduous a fisher as any. Perhaps it is because its bill, being large and clumsy, would offer too great a resistance to the water through which the bird is swimming It can, I think, be safely concluded that this curious habit of holding the bill just beneath the surface of the sea while swimming has nothing to do with drinking

Sea-gulls, although they pass much of their time on the sea, leave it when they wish to bathe and drink There is one small loch beside the Atlantic where gulls are almost always to be seen bathing with relish, and they fly backwards and forwards between this loch and the sea, perhaps several times a day.

The wild whooper swan which arrives in Britain in autumn from Iceland settles at times on the sea, but is never happy on the salt water, although its relative, the smaller Bewick's swan, passes most of the winter season on the brackish lochs and estuaries of the Hebrides Ducks appear to drink frequently, but wild geese at their winter haunts must be able to go some time without water, for some of the sea-girt isles where they live have no fresh water upon them

The grey or hooded crow is detested by game preservers because of its habit of stealing eggs Especially when the grey crows have young in the nest they hunt far and wide for the eggs, not only of grouse but also of much larger birds, and I have known them suck a nest of a grey lag goose's eggs in a single day. It is possible that this egg stealing is partly to provide the young birds in the nest with as much liquid food as possible, and one can understand why young hooded crows should be able to exist without water But the twite, which feeds its young on seeds, the siskin, the linnet and other passerine birds—how is it possible that the broods of these birds should live without water during their time in the nest? The passerine birds which feed their young on hard and dry seeds do so by regurgitation They swallow the seeds, and later present them to their young moistened, and impregnated with their digestive saliva Those which feed their young on insects and other juicy living food feed them directly, without regurgitation

Dr. Glover Allen, in his book "Birds and their Attributes" referring to the drinking habits of North American birds, writes .

> "In the far north water may be unobtainable throughout winter, but it may be possible for northern birds to subsist on snow I have known pine siskins to eat snow and once watched a flock of Cedar Waxwings engaged in catching snowflakes during a storm, flying up and snapping at them as if they were insects Here is a subject on which more information might easily be secured "

Elsewhere Dr Allen remarks ·

> "A final word as to the drinking habits of birds, which have not perhaps been sufficiently studied. We have all noticed that hens and sparrows sip from a pan, raising their head between each sip as if to let the drop trickle down their throats The quite different manner in which pigeons thrust in their bills and pump in the water like a horse cannot have escaped the attention of most We do not know much as to the amount of water birds need and how often they drink It is said that prospectors in desert country are often able to locate springs by watching the flights of doves or pigeons which must drink daily and fly in from the surrounding country regularly for the purpose
>
> "Most sea birds are known to drink salt water in preference to fresh, indeed captive gulls may die without it Land birds, however, need fresh water No doubt some species must go long periods without drinking, as in case of certain birds that incubate continuously, for example, the female Hornbill that is walled up in her nest cavity and fed by her mate "

In "Jungle Side", a natural history account of Ceylon, by John Still, are some interesting remarks on the drinking habits of birds. The author writes .

> " the lovely paradise fly-catcher who nests in some garden in the nor'-east monsoon can be found passing the sou'-west as a visitor to a water-hole. Others are permanent forest dwellers, like the wonderful long-tailed robin whose song is the sweetest in all Ceylon, and another rather rare little bird who often owns a water-hole to himself, the three-toed kingfisher, whose gay habit it is to have rosy plumage where most of his tribe have blue "

Observations by trained watchers on the drinking habits of birds are, however, very meagre, and the whole fascinating subject would certainly repay more close observations

---

Joachim Barrande and his Palæontological Work

By JAN KOLIHA, Curator of the Barrandeum, National Museum, Prague

A LITTLE more than fifty years ago, on October 5, 1883, the death occurred of Joachim Barrande, who was one of the greatest palæontologists of the second half of the nineteenth century. Barrande was born on August 10, 1799, on the estate of his family at Sangues (Dept. Haute Loire). He studied at the Paris Polytechnic School Besides lectures of a purely technical nature on bridge- and road-construction, he attended those on geology, zoology and botany. His teachers were G. Cuvier, A. Brongniart, de Jussieu, C. Prévost, de Blainville, G. St. Hilaire, Serres, Audouin and others.

Soon after Barrande left the Polytechnic, he was called to the French Court, to act as tutor in natural science and mathematics to the hereditary Prince Henri, Count Chambord, grandson of Charles X When the Bourbon family was expelled from France, after the revolution of July 1830, Barrande also went into exile with them. After a short stay in Edinburgh, the royal family came to Bohemia, first of all living at Buštěhrad Castle (west of Prague) and then at the Castle, Prague (that is, Hradčany, the old royal castle of the Czech kings) From this time onwards, Barrande remained permanently in Prague.

In 1833 Barrande gave up his position as a tutor, and devoted himself to engineering. He was entrusted with the surveying of a projected line, which was a continuation of the horse route, from Křivoklát, along the River Berounka, to the coal basin of Radnice and then on to Plzeň.

During this work, Barrande found a number of beautifully preserved fossils, in Middle Cambrian shales, in the neighbourhood of Skryj and of Tejřovice. By these discoveries he confirmed his view, that strata exist in Bohemia similar to those which Murchison had studied in Wales and Scotland. When the first part of the latter's "Silurian System" appeared in 1839, Barrande decided to investigate systematically all the so-called Transition Strata and their fauna in Bohemia, being certain that the Silurian formation of Bohemia was the same as that in Britain.

Finally, after many years of investigation and collection, Barrande began the publication of his "Système silurien de la Bohème" (1852), a work which even to-day is the only one of its kind in palæontological bibliography. The author published between 1852 and 1881 twenty-two big quarto volumes, partly containing text, partly plates. The treatise contains more than 6,000 pages of descriptions and 1,160 plates of fossils. The first volume, in which he deals with trilobites, forms, together with the supplementary parts, the most important and best account of these extinct crustaceans in general. Barrande also gives a careful description and illustration of the geological conditions in the older Palæozoic rocks of Bohemia. He divides the "Silurian" into eight series, indicated by the letters A to H. He determines the order of succession, the relations of deposit, and the fossiliferous contents of all his stages, based on their palæontological connexion with the British Silurian. In this and in the following volumes of his work, the author describes in turn the other crustaceans besides trilobites, and the fishes, cephalopods, brachiopods and lamellibranchs known up to that time in Bohemia.

It is clear from his palæontological work that Barrande was a convinced believer in the constancy of species (being a pupil of Baron Cuvier), and therefore an opponent of the theory of evolution. It is well known that his objections were among the most weighty of those which were ever expressed against that theory.

While issuing his chief work and several lesser publications, Barrande spent much time in defending his theory of so-called 'colonies', which were supposed to be intercalations of parts of a later geological fauna in strata containing an older geological fauna, the result of migrations. Barrande, from 1861 until 1881, was at war with many well-known geologists, and to the day of his death was never shaken in his opinion of such migrations of faunas. He defended his view by the publication of polemical articles, letters and longer works, which were gathered into five parts and entitled "Défense des Colonies". The chief opponents of Barrande's views were Prof. J. Krejčí, the father of Bohemian geology, V. M. Lipold, the Viennese geologist, and J. E. Marr, the English geologist, who explained these phenomena as due to faulting of the strata.

Barrande also took part victoriously in the dispute concerning the independence of the so-called Taconic System in North America, ending a discussion of many years by proving that the fauna which was discovered by Emmons and Marcou represented his primordial Cambrian fauna.

Meanwhile, great uncertainty prevailed both in the Bohemian National Museum and in the Czech University as to what would be the fate of the huge collections of fossils made by Barrande. Various negotiations took place, letters were written to Barrande, and a promise was obtained that his collections would be installed in the new building of the National Museum. When Barrande's will was opened, it was discovered that the National Museum had become the heir of all his collections, of all his manuscripts, and of his scientific library. By this splendid bequest, the National Museum of Prague has become the owner of one of the greatest collections of older Palæozoic fossils, and as such is the most important goal of all geologists and palæontologists who study the oldest fossiliferous rocks.

Obituary

Prof. Sven Odén

It was with the deepest regret that we heard of the death of Sven Odén. He had for some time been in failing health, but his friends still clung to the hope that his vigorous vitality might win. Unfortunately this was not to be, and he died on January 16 in his forty-seventh year.

Odén was trained under Svedberg and was soon recognised as an exceptionally able colloid chemist. His first investigation, published in 1910, was on the coagulation of colloidal sulphur, and it brought out the important fact that small variations in the hydrogen ion concentration of the solution greatly influenced the critical concentrations of electrolytes that just brought about coagulation. This group of problems interested him throughout the whole of his life and he constantly reverted to it. In 1911 he began an important series of investigations on the size of the particles in the suspension, determining the mass of the particles lying between successive size limits. This led him to a study of fractional coagulation. All this work he pursued with great ingenuity, using as his materials such varied substances as clays, deep sea deposits, cements and various precipitated substances. Having an unusually wide outlook, he was able to apply his results not only to problems in the pure science of colloids, but also to problems of applied science.

Nothing better illustrates the genius of Odén for attacking a difficult problem than the automatic balance he made for use in sedimentation investigations. By its means he was able for the first time to construct curves showing the mass distribution of particles between any desired limits of size in a mixture of various sizes Readers in Great Britain are familiar with some of these curves, especially those in his paper in the *Proceedings of the Royal Society of Edinburgh* in 1911 on the size of the particles in deep sea deposits, and in the *Proceedings of the Royal Society* of 1924 when, along with a group of Rothamsted workers, his colleagues during a period of extended leave spent at Rothamsted in 1923, he developed more fully this automatic balance and worked out typical distribution curves for clay particles of different sizes The subject is discussed fully in Dr B A Keen's monograph, "Physical Properties of the Soil" Later work at Rothamsted showed certain unforeseen sources of error not yet overcome which detract from the strict quantitative interpretation of the results Whether they can be avoided or not, the work stands out as the first and best study of distribution of clay particles according to size

A second group of investigations in which Odén achieved marked success dealt with peat He began about 1916, and by 1919 was able to publish his monograph "Die Huminsäuren", one of the best that has ever appeared on that particularly difficult and elusive group of mixtures Applying for the first time the methods of modern physical chemistry to the black sticky mixture of humus substances soluble in alkalis and reprecipitated by acids, he gave for the first time definite proof that the so-called humic acid really is an acid and he was able to assign to it fairly definite properties including tentative molecular and equivalent weights Considerable discussion has followed, and there has been in consequence of his work much clearing up of a very involved subject In addition to these physico-chemical investigations he also studied the possibilities of obtaining fertilisers by the use of peat its use as a source of ammonium chloride and for rendering mineral phosphates soluble

Another investigation in organic chemistry made by Odén, in conjunction with E Fischer, was the synthesis and study of sugar derivatives having molecular weights ranging up to 8,000

Up to this time Odén had been working at Uppsala, first (from 1913) as lecturer in chemistry, and later, in 1920, as professor of inorganic chemistry at the Technical Institute of Engineering In 1925 he became head of the Chemical Department of the Central Experimental Agricultural Station, Experimentalfältet, which post he held until his death Here he turned his attention to the exchangeable bases in the soil, which he studied by electrodialysis His last papers were on the application of electric light to the furtherance of plant growth, and the relations of certain organic compounds and the growing plant

Odén was not only a brilliant investigator but also a delightfully human personality, a man one loved to meet and talk to, full of ideas, overflowing with energy and vitality Whatever he touched he illuminated, and the more difficult the subject the more it attracted him and stimulated his inventive powers Sweden has lost a distinguished son and science a brilliant worker.

E J RUSSELL.

DR LILIAN CLARKE

THE death of Dr Lilian Jane Clarke, at the age of sixty-eight years, marks the passing of the pioneer of the best modern methods of the teaching of botany and Nature study in schools The subject early attracted her and having gained the gold medal of the Apothecaries' Society for botany and entered University College, London, in the session 1887–88, she took her B Sc degree in 1893–94, after studying botany under Prof F W Oliver She was appointed science mistress at James Allen's Girls' School, Dulwich, in January 1896, and from that time onwards devoted herself whole-heartedly to developing her own ideas of botanical teaching

The 'laboratory' Dr Clarke found in 1896 at James Allen's was a tray of apparatus on the hall platform, the laboratory she left was a well-equipped building for botany and other scientific subjects, with a greenhouse for biological experiments, and a large area of land laid out in the botanical gardens for which the school is justly famous, and with which Dr Clarke's name will always be associated These gardens started with a few natural order beds, but as her method of direct teaching of Nature study was developed, more land was gradually acquired for the study of plant physiology and ecology At first the financial difficulty was great, but eventually the value of the gardens was recognised by a small grant which permitted further extensions. The work throughout was done almost entirely by the voluntary labour of the school pupils in their spare time, and with their aid Dr Clarke built up a range of gardens unparalleled elsewhere Order beds, plots for genetical and physiological experiments, shingle bank, bog garden, pond, a lane with its hedgerows and even an oak wood were all finally acquired, and provide a wealth of material for teaching purposes The value of her pioneer work in this direction was recognised in 1902 by the award of the degree of D Sc (Lond), and in 1905 she was one of the first women admitted as a fellow of the Linnean Society

Somewhat of a martinet in her laboratories, Dr Clarke instilled habits of carefulness and accurate working into her pupils, which many of us have since fully appreciated The secret of her success was unbounded enthusiasm and driving power, coupled with the ability of interesting individual students in particular details of the work, making even the drudgery appear worth while Compulsory retirement under the age limit went sorely against the grain, but to the end she maintained her interest in the work of James Allen's School and of many of her old students, whose careers she followed closely.

As secretary in 1921–26 of the Education Section of the British Association Dr. Clarke did further work for the improvement of teaching methods; she was also chairman of the committee on the teaching of general science in schools, with special reference to the teaching of biology.

Apart from her botanical work, Dr. Clarke had a wide knowledge, and love for, Old London, and only two years ago she founded the London Wanderers Club among old J.A.G.S. girls, herself acting as leader on periodical rambles, sparing no time and trouble in their successful organisation. The esteem in which she was held by her old students was marked last year by the foundation of a "Lilian Clarke" botany prize fund at James Allen's School, and no more fitting tribute to her memory could be raised than an extension of this fund for the further encouragement of the subject for which her life was spent Her affection was fixed on Dulwich, and by her special request the first part of the funeral service was held in the old College Chapel, in the presence of the upper school and her friends and colleagues.

WINIFRED E BRENCHLEY.

MR R. J. MOSS

THROUGH the death on January 27 of Mr. R J Moss at the age of eighty-seven years, the Irish scientific world has lost one of its last links with the brilliant period of which FitzGerald was the leading spirit Moss was appointed keeper of the minerals and analyst to the Royal Dublin Society in 1875, and registrar in 1878, a position which he held until his retirement in 1921 He was the oldest member of the Royal Irish Academy, having been elected in 1874

Despite his onerous routine duties, Moss published many original papers, chiefly on chemical subjects Among these may be mentioned those on cobalt chloride as a moisture test, on an improved method of determining the gases dissolved in water, and on the state in which helium exists in pitchblende In the last he employed an ingenious method of extracting the helium by grinding the mineral *in vacuo* He also investigated some archæological problems His last paper, read before the Royal Irish Academy in 1926, deals with a chemical examination of some ancient metallurgical crucibles. From his analyses he arrived at important conclusions as to the metallurgical knowledge of the ancient Irish

Moss, however, like so many scientific men of his period, did not restrict his work entirely to one branch of science. His earliest work, carried out in collaboration with H. N Draper, dealt with the photoconductivity of the allotropic forms of selenium. He published papers on the spheroidal state and in 1896 investigated the effect of X-rays on the combination of hydrogen and chlorine and on the fluorescence of various salts

It is perhaps for his work in the foundation of the Irish Radium Institute that he will be longest remembered. When Joly first proposed his method of using radon in fine glass capillaries for therapeutic purposes, Moss designed and constructed the requisite apparatus. In this his skill as a glass-blower and his knowledge of handling small quantities of the rare gases were a great asset. The original apparatus was used for many years at the Institute. During the War he, and his two assistants Messrs. Stone and Deane, carried out all the work of the Institute, and large quantities of radon were supplied to various military hospitals, mainly for the treatment of wound scars.

To those who knew Moss only in his later years, one of his most striking characteristics was the extreme ease with which he carried their burden. To the last he was a valued member of the Irish Radium Institute Committee and a regular attendant at scientific meetings Of him, I think, we can use, in its best sense, the saying He, whom the gods love, dies young

J H J POOLE

PROF. T. ERIC PEET

WE regret to record the death on February 22 at the age of fifty-two years of Thomas Eric Peet, reader in Egyptology in the University of Oxford.

Eric Peet was educated at Merchant Taylors' School, of which in later life he became a governor, and at Queen's College, Oxford, where he was Jodrell scholar and graduated with second class honours in Classical Moderations and *Literæ Humaniores* In 1906 he was awarded a Craven fellowship and entered the British School of Archæology in Rome, later holding the Pelham studentship The results of his researches were published in 1909 in "The Stone and Bronze Ages in Italy and Sicily", a book which is still recognised as a standard authority

Peet then turned his attention to Egyptology, and this remained his principal occupation for the rest of his life He excavated in Egypt at Abydos, at first under Prof Garstang and then as assistant to Prof Naville, on behalf of the Egypt Exploration Fund, collaborating in vols 1–2 of the valuable memoirs on the cemeteries of that site He also collaborated in a publication on the inscriptions of Sinai A work entitled "Rough Stone Monuments and their Builders" appeared in 1912 In the following year Peet was appointed lecturer in Egyptology in the University of Manchester

After the War, in which Peet served with the King's (Liverpool) Regiment in Salonika and France, he resumed excavation in Egypt on behalf of the Fund at El-Amarna, publishing "The City of Akhenaton", vol 1 in 1923. His "Egypt and the Old Testament", a book of more general appeal than his other works, had appeared in 1922, and in the meantime he had also devoted attention to the study of papyri, more particularly those of a mathematical character, the result appearing in publications issued from 1920 onwards, dealing with the Rhind, Mayer and other papyri On Prof. P. E Newberry's retirement from the

Brunton professorship in the University of Liverpool in 1923, Peet was appointed to succeed him, and in the same year was elected Laycock student of Egyptology of Worcester College, Oxford. From that time onward Peet ceased to take an active part in field work, but devoted himself to teaching and research, also editing the *Annals of Archæology and Anthropology* (Liverpool) and the *Journal of the Egypt Exploration Society* His "The Egyptian Dynasty" appeared in 1930 and his Schweich Lectures, on "Comparative Study of the Literatures of Egypt, Palestine and Mesopotamia", in 1931. On the retirement of Prof F Ll Griffith from the chair of Egyptology at Oxford last year, Peet was appointed as reader, being also elected to a fellowship by his own college

At the very outset of his career, Peet was recognised as a brilliant archæologist, and at no time did his performance fall below expectation

WE regret to announce the following deaths.

Dr F A Bather, F R S, formerly keeper of the Department of Geology, British Museum (Natural History), on March 20, aged seventy-one years

Prof Davidson Black, F R S, professor of anatomy in Peiping Union Medical College and honorary director of the Cenozoic Research Laboratory, National Geological Survey of China, on March 15, aged forty-nine years.

Prof F Ll Griffith, emeritus professor of Egyptology in the University of Oxford, on March 14, aged seventy-one years

Dr Walter Rosenhain, F R S, formerly superintendent of the Department of Metallurgy and Metallurgical Chemistry in the National Physical Laboratory, on March 17, aged fifty-eight years

News and Views

Liquid Crystals

WE are publishing as a special supplement this week an account by Sir William Bragg, director of the laboratories of the Royal Institution, of those substances which in Great Britain are usually called 'liquid crystals' Their very striking appearances on the microscope stage are fairly well known, but this is the first time that a coherent story has been made of the optical principles by which their characteristic behaviour is exhibited The authors of even the most modern books on optics have not given this matter their attention, and until recently only superficial notice had been taken in Great Britain of this class of substance. The examination and explanation of their behaviour links them on one hand to the large class of oriented liquid films, and suggests on the other hand that more regular structure which X-ray analysis is daily revealing to us in so many directions By means of new photographs, diagrams and drawings of models, Sir William Bragg has with appealing directness given us a statement of the problems which these bodies have yielded The optical behaviour of the main groups is thus seen to be related to a varying degree of regularity of arrangement while in the mobile phase. Sir William's article, which gives a clear picture of the subject without going greatly into detail, will provide a stimulus to the growing interest which Friedel's 'mesomorphs' are attracting among physicists and others in Great Britain

Sir Robert Greig

SIR ROBERT GREIG, Secretary of the Department of Agriculture for Scotland, is about to retire from that position, as he attains his sixtieth year on March 23. He has only held the post for about five years, but that has been long enough for him to prove himself an excellent chief who has backed all scientific development in his Department. After leaving the University of Edinburgh, Sir Robert was for a time a ranch manager in north-west Canada After returning to England he was for two years lecturer at the Cheshire Agricultural College, passing on for four years to the Durham College of Science. In 1903–10 he was the Fordyce lecturer in agriculture at the University of Aberdeen In 1911 he returned south to become staff inspector in agriculture at the Board of Education, but not for long, for in the same year he became a commissioner at the Board of Agriculture, Scotland, of which body he was chairman in 1921–28. The combination of technical knowledge and administrative ability exemplified by Sir Robert goes far to explain his success, and general regret is expressed at his impending retirement.

Technical Officers and Administrative Posts

ON or about the same date that Sir Robert Greig retires, one of the four assistant secretaries of the Scottish Agriculture Department is also due to retire, in the person of Mr. H. M Conacher. It may almost be assumed that their successors will be Scotsmen, or there would be 'wigs on the green' at Westminster It is to be hoped also that on this occasion full consideration will be given to the claims of technical officers in Government departments to be selected for these posts, instead of assuming, as is usually done, that they cannot be capable administrators The functions of the Scottish Department of Agriculture are of a character which render technical knowledge and experience, in addition to administrative ability, highly desirable qualifications for the controlling posts. The Department's work is largely concerned with the scientific development of agriculture, the organisation of agricultural education, and the carrying out of schemes of land settlement. For these purposes it employs a variety of technical experts, and it is not too much to ask that senior members of these technical staffs should definitely be brought under review in the filling of the impending vacancies in the controlling posts.

Rothamsted Experimental Station

ROTHAMSTED must surely have appeared to most of its scientific visitors as the embodiment of stability, and it has come as a great shock to learn that its historic fields are threatened by the builder. When Lawes in 1889 set up the trust that governs the Station, he did not give the classical experimental fields or the land on which the laboratories stand, but only the use of them for a period of years. After his death it was found impossible to work the experiments without taking on the Home Farm from the family trustees, and this was done in 1911, but some of the highly important fields were let to Rothamsted on a six monthly arrangement only. Even so, the farm remained awkward and difficult to work, being split into three separate pieces, easy access to which was possible only by courtesy of the estate and the tenant. With the encroachment of the builder a new situation has arisen. The family is proposing to give up possession and to put the whole estate into the market. The situation has been closely examined by the Lawes Agricultural Trust Committee in consultation with the staff of the Ministry of Agriculture, and the conclusion has been reached that Rothamsted must own the land on which it is working. An appeal for £30,000 has therefore been issued over the signatures of an influential group including the Duke of Devonshire, the presidents of the Royal Society, the Royal Agricultural Society, and the National Farmers Union, Lord Clinton, the chairman of the Rothamsted Committee, Sir Daniel Hall, the late director and Sir John Russell, the present director of Rothamsted.

IT is greatly to be hoped that the appeal may succeed. The sum required is not large having regard to the area of land involved (515 acres) and to the fact that the purchase includes also Rothamsted Manor House, a Jacobean mansion, without which, it is understood, the land could not be acquired. Rothamsted has a record of more than ninety years to its credit; its first triumph was the discovery of the value to agriculture of artificial fertilisers, and of the way to make them on the large scale; it was on the Rothamsted fields that they were first tried on the large scale, with the result that the fertiliser manufacturing industry in various countries now has an annual output of some 35–40 million tons. It is not, however, because of past triumphs that Rothamsted deserves to survive. With a staff of some sixty scientific workers, it is an active centre of research on agriculture, soils, fertilisers, plant nutrition, statistical methods in biological science, plant pathology, entomology, and bees, while from its laboratories there has gone forth a steady stream of young men and women to take up high posts in practically all the more important agricultural research institutions in the Empire. Further, agricultural experts from all parts of the world go to work in its laboratories, to study its methods and its results. Its essential characteristics are the spirit of co-operation between the various departments which greatly facilitates border-land work, and the close connexion between field and laboratory, which it is now hoped to put on to a permanently secure basis.

Mr H. Dennis Taylor

THE council of the Physical Society has awarded the eleventh Duddell Medal to Mr Harold Dennis Taylor. This medal is given "to persons who have contributed to the advancement of knowledge by the invention or design of scientific instruments, or by the discovery of materials used in their construction". Mr Taylor has lived and worked in a period which must always be regarded as of the first importance in the development of optical instruments. The work of Abbe and Schott may be said to mark the beginning of the modern period in lens construction. At this time, Dennis Taylor was the optical manager of Thomas Cooke and Sons, of York, a firm celebrated for its astronomical and surveying instruments. Large astronomical refractors of that period suffered from a serious defect, the so-called secondary spectrum, a residual defect remaining when the normal conditions for the removal of chromatic aberrations have been satisfied. Taylor removed this defect by employing three glasses, and with rare skill and insight devised an objective in which not only the purely optical problem was solved, but also the important practical problems of giving accuracy of form to large lenses of different shapes, and allowing for their deformation in use. In these first triple apochromats, the colour correction is so good, and is so successfully combined with the other fine corrections needed, that the same instruments may be used both for visual and for photographic work. A number of large telescopes of this type are in regular use, among them two, of apertures 12½ in. and 12 in., at Cambridge; other 12 in. instruments of this design are in use at Rio de Janeiro and at Kodaikanal in India.

IN 1893 Mr Taylor took out two patents for photographic lenses, which were later put on the market as the well-known Cooke lenses. In the specifications of these lenses, nothing is more striking than the treatment of the theory which leads to the method of eliminating coma simultaneously with curvature and astigmatism. In later years Mr Taylor has not lost the skill and originality he displayed in his earlier inventions. Many of these fall outside the field in which physicists are specially interested. Mention should, however, be made of the telescope in which he showed that it is possible to combine a large aperture and a large field of view with freedom from aberrations comparable with that attained in the Cooke lenses. This is undoubtedly an achievement of the first order, and may prove of great value in scientific work. Mr Taylor has not only made outstanding advances in the construction of lenses, but he has also written a systematic treatise, "A System of Applied Optics", which will enable the physicist of the future to understand the scientific basis on which the art of lens designing rests.

Major John Wesley Powell, 1834–1902

THE centenary occurs on March 24 of the birth of Major John Wesley Powell, the distinguished American explorer, geologist and ethnologist. Born at Mount Morris, New York, of English parents who had emigrated to the United States in 1830, Powell was educated at Illinois and Oberlin College He served in the army during the Civil War, losing an arm at the battle of Shiloh, and in 1865 became professor of geology in the Illinois Wesleyan University at Bloomington Two years later he began a series of hazardous and important expeditions to the Rocky Mountains and the Green and Colorado Rivers, which led to a Government geographical and geological survey of the Rockies Powell served on this for several years and his reports, together with those of F V Hayden and G M Wheeler, were embodied by Clarence King in the United States Geological Survey bulletins In 1879 Powell was made director of the United States Bureau of Ethnology, and in 1881, on the resignation of King, he became also director of the Geological Survey He held the latter post for thirteen years, but retained the former until his death at Haven, Maine, on September 23, 1902 Powell was one of those pioneer geologists of the Far West, who as von Zittel said, "by their vivid portrayal of the work of subaerial denudation roused the intellectual life of the middle of the century to new conceptions on a grand scale "

The Electron in Electrical Engineering

MR C C PATERSON gave on March 15 the Faraday lecture to the Institution of Electrical Engineers, choosing as his subject "The Electrical Engineer and the Free Electron" It was the kind of lecture that one could have imagined Faraday himself to have given, consisting of lucid explanations and practical demonstrations of fundamental principles Mr Paterson stated that the science of electrical engineering was born again when the physicist showed how electricity could be liberated from metal In the free state it has potentialities of which no one dreamed before its discovery by Sir J J Thomson Just as physiologists learned that disease can be envisaged in terms of isolated germs and their life-history, so the physicist found that electricity can be thought of in terms of the individual electron, its habits and affinities Two of the main reasons for the practical usefulness of electricity are the ease with which it can be transported and the ease with which it can be controlled In the latter respect the free electron has now given the engineer new and extraordinary power Many applications have been already revolutionised and there are doubtless many more surprises in the future The secret is that a stream of free electrons, whether in a vacuum or a gas, can be manipulated with such facility that the electrical energy output can be reversed at the rate of millions of times a second Alternatively, it can be made to fluctuate at any given slow speed. While the agency which imposes this control on the electron stream is usually itself electrical, it is possible to control it by light, magnetism or heat

NORMALLY the electrons are confined within metal conductors When a portion of a circuit (a thermionic valve cathode or filament) is heated, electrons emerge freely, like water pouring through a porous section of hose pipe Heat is the agent which liberates the electrons from the interior of the wire. They swarm in a thin layer round the outside surface, ready to be attracted away by externally applied electrical forces exerted by another metal electrode As the electrons travel between the electrodes, the control causes them to flow or ebb, reverse or oscillate. Frequencies up to 3,000 million per second are attainable The photoelectric cell is another liberator of electrons In this case they emerge from a sensitised cold surface (cathode) where light falls on it, and are collected on the anode These cells are capable of receiving more than 300,000 impulses per second Mr Paterson explained and demonstrated the way in which sound and speech are reproduced in various devices He said that the electron often behaves as if it were a solid particle, but under other conditions it appears to be a group of waves It acts the same whether it has the particle or the wave characteristics In free space it acts like waves, but when it collides with something it has particle characteristics The filament of the incandescent lamp causes the electrons to crowd together and this heats it so much that it gives out light If the electrons escape from the filament its light-giving properties deteriorate, but if the gas envelope is filled with suitable gas mixtures, the escaping electrons collide with the gas atoms and produce a brilliant and highly efficient light source This is the principle utilised in luminous gas discharge tubes Cold cathode tubes need a high voltage to induce the electron stream, but a hot cathode produces a much more copious stream and enhances the brightness of the light Some of these luminous tubes produce twice as much light as an ordinary filament lamp taking the same power

Excavations at Ur

OWING to the late date at which excavations were resumed at Ur this year, Dr C L Woolley's first report on the season's work has only just been received and is published in the *Times* of March 16 The operations of the joint expedition this year are to be directed to the exploration of a cemetery of the Jemdet Nasr period of about 4,000 B C, which lies at a depth of 54 ft below the surface and involves the removal of about 5,000 tons of accumulated rubbish The three weeks' work which had been completed at the time Dr Woolley wrote has produced a remarkable example of sculpture in the round in the form of a woman's figure in alabaster with lapis lazuli inlay forming a fillet outlining the face, lapis lazuli and shell eyes, bituminous inlay for the eyebrows, which meet above the nose, and hair in dark paint The statue is ten inches high. It is not only the earliest known example of sculpture in the round at Ur, dating from about the last quarter of the fourth millennium, but it is also remarkable as being the first statue to be found in a grave It lay in a soldier's grave, close to his head and touching the blade of a bronze axe which he carried over his shoulder This grave is situated in what would appear to have been a military cemetery in the latter half of the Royal Cemetery period. This at least is the inference which Dr. Woolley draws from the number of battle axes, adze-shaped axes and daggers which have been found in this area. An interesting feature in the economy of the city is conjectured to interpret the existence in the very heart of the town of an area which throughout the history of Ur was a mere rubbish heap. A section shows that while this rubbish heap was continually receiving additions, it was at the same time constantly being removed to provide material for the terraces on which new buildings were erected.

Early Art at Giza

AN interesting account of the excavations of the Egyptian University at Giza during the present season is given by the Cairo correspondent of the *Observer* in the issue of March 18. The expedition, of which Prof. Selim Hassan is in charge, is engaged in investigating the Fourth Pyramid, with its surroundings, which has been identified as that of Khunt Kawas, daughter of Menkaura of the Fourth Dynasty. The exploration of the city attached to the pyramid, the only one of its kind yet discovered, has been carried further and has resulted in bringing to light, among other discoveries, the source of the water supply of the libation chamber and above the libation tank the tomb of an official described as "the purifier and prophet of the king's daughter". The temple of Khunt Kawas has been located adjoining the temple of Menkaura and has been cleared. The most notable of the finds here are the base of a diorite statue of the king Chephren, grandfather of the princess, and the torso of a sphinx and the body of a statuette of the king which lay in the entrance to the temple of the king. In a temple of Ankhtef, the priest of the king's *Ka*, were found two small white limestone statues which are said to be the most perfect examples of the statuesque art of the early period. They represent Ankhtef himself seated and a woman kneeling and kneading bread, which, it is thought, may possibly represent his wife. An almost equally notable specimen of this early art is the statue of a judge of the period, which shows remarkable power in the modelling of the muscles and limbs.

Empire Marketing Board Research Commitments

WITH the abolition last year of the Empire Marketing Board, considerable anxiety was felt as to the provision for numerous investigations, in progress and projected, hitherto financed by the Board. Some weeks ago, Mr. J. H. Thomas stated in a written reply to a question in the House of Commons that provision was being made for such investigations (NATURE, Feb. 17, p. 254). In reply to a question by Sir Arnold Wilson asking for more specific information, Mr. Malcolm MacDonald has given the following written answer: "The research schemes financed from the Empire Marketing Fund comprise agricultural and scientific research in the United Kingdom and also in the Dominions, India and the Colonies. It has been arranged for 39 of these schemes, representing an annual cost of approximately £200,000 in all, to be continued, in each case at the same research institution and with the existing personnel. Of these schemes 23 are in the United Kingdom, eight in the Dominions and India and eight in the Colonies. The sum of approximately £115,000 which is required in the next financial year from United Kingdom funds in respect of these schemes will be charged against Votes administered by various Government Departments in this country. The remaining £85,000 is being met by the Governments of the Empire or by the institutions or industries concerned."

Research Under the Agricultural Marketing Boards

IN a written reply to a question by Sir Arnold Wilson in the House of Commons as to what extent the powers conferred by both Agricultural Marketing Acts to adopt schemes for research in the production and marketing of agricultural products have been exercised by the Potato, Bacon, Milk, Pigs, and Hops Marketing Boards, Mr. Walter Elliot, Minister of Agriculture, stated: "The Hops Marketing Board does not possess any powers of the kind referred to. The other Agricultural Marketing Boards mentioned have certain powers which they may exercise in connexion with research services, but I understand they have not yet exercised them." Mr. Elliot said he had no doubt that the Boards in question will give attention to the question of research at the earliest possible opportunity, and that they will approach the Ministry of Agriculture should they think the Ministry able to assist them.

Wool Industries Research Association

THE report of the Council of the Wool Industries Research Association for 1933–34 refers to a 40 per cent increase in fees for private investigations as indication of the growing use which is made of the services of the Association by its members. Income from trade subscriptions has slightly increased, but an income of about £2,000 a year from the Empire Marketing Board has ceased. The activities previously financed by the Board are being continued and efforts are being made to obtain assistance from the Imperial Agricultural Bureaux. At a meeting of the Executive Council of the latter, it was emphasised that the work of the Association at Torridon should be concentrated on investigations of practical value to the grower and to the industrialist, and that Torridon should become a centre from which work on wool utilisation—both as regards research and educational publicity for the Empire as a whole—should emanate. Experiments on the nutritional influences on wool growth have continued in co-operation with the Rowett Research Institute, Aberdeen, and have revealed accentuated differences between a group of sheep fed on a maintenance ration and one receiving a simple supplement of high energy value. Arrangements have been made for further trials of experimental wool packs, including the impregnation of jute packs with rubber latex to anchor the jute fibres so that they do not stray into the wool during transit.

Supplement to NATURE

No 3360 MARCH 24, 1934

Liquid Crystals*

By SIR WILLIAM BRAGG, O M, K B E, F R S

THERE are substances which are liquid in their mobility and crystalline in their optical behaviour The latter property suggests that there must be some degree of arrangement of the component molecules, and the former that this arrangement is readily disturbed though it may be as readily renewed Such substances are generally described as 'liquid crystals' It is argued, especially by Friedel, to whom we owe so much of our knowledge of their properties, that the title is bad, because the substances are neither perfect crystals nor perfect liquids Friedel would call them mesomorphs, which is much more logical, since the conditions to be described are intermediate between other conditions that are well known. The term 'liquid crystals' is, however, simple and suggestive, and those who use it are not likely to be misled

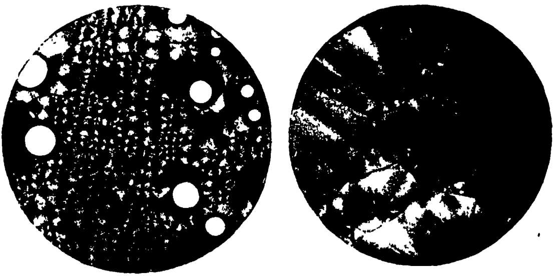

FIG 1 —Enlarged photomicrograph of a liquid crystal A Nicol prism is used as analyser there is no polariser The substance is ethyl *para* azoxybenzoate, temperature 114°–120° C Notice the polygons and the appearances of cones within them The white circles are air bubbles the grey portions are liquid The diameter of the original before magnification is 0 075 cm

The first to give any full and clear account of the properties of liquid crystals was O Lehmann[1] Following him, a number of investigators have attacked the general problem from various sides, Vorlander, Schenck, Friedel, Grandjean, Mauguin, Oseen and others Quite a large literature has grown up round the subject Friedel has given a full account of his experiments in the *Annales de Physique*[2] The present state of knowledge may be inferred from the account of the general discussion on liquid crystals and anisotropic melts held by the Faraday Society in April, 1933[3]

The characteristic properties of liquid crystals are connected with the peculiar form of their molecules These are relatively complicated structures possessing a common feature in their lengthy, chain-like form It is not surprising that such molecules should sometimes exist in a state intermediate between solid and fluid If the form and influences of a molecule can be represented approximately by a sphere, an assemblage of such molecules will resolve itself into individuals at some definite temperature. That is because all the links with neighbouring molecules are similar and break down together But when the molecule is relatively long and narrow, the linkages in different parts of it may be of different strengths Some may be broken at a lower temperature than others There must then be one or more intermediate states of greater but not complete mobility A sufficiently high temperature will bring about the dissolution of the remaining molecular associations, and then a truly liquid state is reached Though the intermediate phases lack the complete ordering of the crystal, that which remains has necessarily its optical effects

---

* From the Friday evening discourse delivered at the Royal Institution on November 24, 1933

It is an important fact that the changes from solid to liquid crystal, and from liquid crystal to liquid, are as sharp and definite as the change from solid to liquid in the more general case

These optical effects possess in many cases a singular beauty, in respect both to colour and to form (*see* Figs 1, 12 and 13*) Most of them, but not all, can be explained in comparatively simple terms which, however, are rarely described in treatises on optics Writers have confined themselves to true crystals and true liquids, and the more complicated problem is discussed only in isolated papers. In what follows a brief account is given of this peculiar optics and of the consequent inferences as to the liquid crystal structure

SMECTIC CRYSTALS

Friedel divides liquid crystals into three classes in his own words, there are three mesomorphous phases The first of these he calls 'smectic', thereby implying a parallelism with the soaps Their special feature is their stratification In each layer the molecules are arranged side by side, like corn in a field, the thickness of the layer being the length of the molecules In the case of the soap bubble or film, we have such layers forming the surface inside and out The side to side attractions of the molecules bind them together, so that the film has a certain surface energy of tension If the film is made to grow larger in extent, other molecules of the sodium oleate slip into their places and increase the area If the film contracts, molecules drop out and go back into the liquid

Let us suppose now that such layers are formed in the substance ethyl azoxybenzoate, which shows the smectic phenomena very well Each sheet is very flexible If such a sheet could be suspended in space, free from gravity, it would take the form of a perfectly flat surface because the molecules would tend to lie parallel to one another Their side to side attractions are relatively strong If bent, it would straighten itself out again If a number of such sheets were put together like the leaves of a book, they would tend to adjust themselves further, so that the ends of the molecules on the face of one sheet fitted exactly in some characteristic way on to the ends of the molecules on the next sheet In this way the solid crystal would be formed, in which there is arrangement and regular repetition in every direction in space But in the smectic state the temperature is high enough to ease the bonds between sheet and sheet, and yet not high enough to break up the sheets themselves A single sheet does not necessarily behave like a separate crystal it is rather to be considered as a two-dimensional fluid

$$C_2H_5-O-CO-C_6H_4\ \underset{O}{\underbrace{N-N}}-C_6H_4-CO\ \ O-C_2H_5$$

Ethyl *para*-azoxybenzoate
Solid – 114° – smectic – 120° – liquid

A sheet of this nature can slide without hindrance on its neighbours When a film of the above-mentioned substance is stretched over a small hole in a plate, the condition of parallel layers is in fact arrived at It can also be reached when the substance rests on a plate, but unless the plate is carefully prepared it is apt to be interfered with by local attachments, as will be seen presently In the simple form the substance may be examined in polarised convergent light, and will show the usual rings With the aid of a quarter-wave plate it can be shown by well-known methods that the arrangement simulates a positive crystal The full structure of the crystal is not realised because the separate sheets are not properly adjusted to each other That, however, does not affect the examination in convergent light, which requires only that the axis of the beam shall be perpendicular to the layers The experiment shows that the substance behaves like a positive crystal, such as quartz In other words, the frequency of the light vibrations perpendicular to the layers (and parallel to the molecules) is less than the frequency when the vibrations are not perpendicular thereto This is to be expected, because it is always found that vibrations along an extended molecule are slower than those across it

The simple stratification lends itself also to study by X-rays, when it appears that the thickness of the layer agrees closely with what we know of the length of such molecules, based on exact X-ray measurements of other organic molecules Friedel' gives the value 19 9 A In the solid crystal the thickness of the layer is found to be 16 2 A The difference is due to the fact that in the layers of the solid the molecules are inclined and not upright as in the liquid crystal

---

* The photographs are due to Mr W J Green

In general, however, the substance, when placed between glasses, as is usual when examination is to be made under the microscope, and when raised to the proper range of temperature, or cooled from the melt, does not assume the simple form The strata are crumpled Attachments between substance and glass are strong, and at various points these attachments compel the arrangement of the molecules in different directions The general arrangement has to accommodate itself to enforced conditions in various places Moreover, nuclear associations of molecules are formed at various points in the liquid when it is passing into the liquid crystals phase , and these must be fitted to one another as they grow and meet together There is something like the contortion of strata in a geological formation , but the smectic arrangement is simpler, because the layers, while preserving their thickness exactly, can slide easily over one another and so can adjust themselves to surface conditions

The optical peculiarities of the smectic state are caused by these contortions of the strata We have therefore to consider in the first place the forms which the strata assume, and in the second their effect upon the transmission of light

From direct observation it can be inferred, as will be seen presently, that the surfaces of the strata form series of the 'cyclides' examined long ago by Dupin and known by his name We must therefore consider their chief properties

The locus of the vertices of the circular cones (cones of revolution) passing through a given ellipse is a hyperbola which passes through the focus of the ellipse and lies in a plane perpendicular to that of the ellipse Conversely, the ellipse is the locus of the vertices of circular cones passing through the hyperbola The ellipse and the hyperbola are described as 'focal conics'

Surfaces can be drawn which are at right angles to all the straight lines which pass through both conics These are Dupin's cyclides They are peculiar in that any pair of surfaces is equally separated everywhere, the distance of separation being measured along the common normal Obviously this makes it possible for the surfaces to coincide with the surfaces of sheets of uniform thickness.

It is easy to form an idea of the arrangement by considering a simple case The ellipse may become a circle, in which case the hyperbola becomes the axis of the circle, that is to say, a straight line passing through the centre of the circle and perpendicular to its plane The cyclides become 'anchor rings' or 'tores', intersected at right angles by every straight line that meets both circle and axis The construction is shown in Figs 2 and 3

When this simple case occurs in the liquid crystal, the strata are bounded by a succession of anchor rings equally separated The straight lines that meet both circle and axis are perpendicular to the strata and therefore parallel to the long dimension of the molecule As has been said above, the substance behaves like a uniaxial crystal, the axis lying along the molecule The straight lines show therefore the direction of the optic axis at every point, being parallel to the molecules round about the point It must not be supposed, however, that each such straight line is a chain of molecules , if that were the case converging lines of molecules would 'jam' into one another

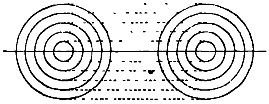

FIG 2—Section of an anchor ring in layers, which constitute a particular series of Dupin's cyclides

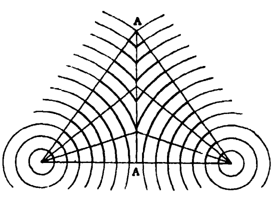

FIG 3—An axis *AA* is now added to the ring of Fig 2 Every straight line drawn from any point on *AA* to any point on the axial circle of the ring meets every layer at right angles In this figure emphasis is laid on those parts of the layers which lie within the cone of which the upper point *A* is the vertex and the axial circle is the circumference of the flat base Within the cone the layers are in equilibrium with each other How one cone can be fitted to another is explained in the text

It will be observed that no two of the straight lines intersect We may pass from this special case to the general by imagining the circle to become an ellipse and the cones to be pushed over to the side as in Figs 4 and 5 The anchor rings become distorted, but the characteristic properties of the cyclides are still maintained Every straight line that meets both ellipse and hyperbola is normal at all points to a series of surfaces, and still any two of the surfaces are everywhere separated by the same distance, measured along the common normal

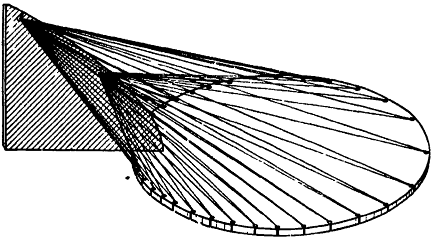

Fig 4 —A drawing of a model made to illustrate the structure of the interior of an oblique cone containing the smectic substance The two sheets of zinc are cut into the form of an ellipse and part of a hyperbola, and are fastened together so that their planes are perpendicular to each other and each curve goes through the focus of the other Slots are cut as shown, and strings join two points on the hyperbola to a number of points on the ellipse If the ellipse were made into a circle, the hyperbola would become the axis of the circle as in Fig 3 The strata, having the form of Dupin's cyclides, intersect every one of the strings at right angles

If now we take any two points on the hyperbola, of which one may be the focus of the ellipse, and draw from each of them straight lines to every point on the ellipse, we include a region bounded by two cones, or in the special case one cone and its flat base, which can be divided by Dupin cyclides into a series of sheets of uniform thickness, and at all points on the surface of the space the sheets are perpendicular to the generators of the cones

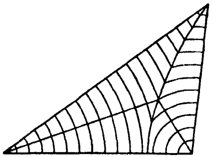

Fig. 5 —A section of Fig. 4 in the plane of the hyperbola, showing parts of cyclides. Compare this with Fig 3 The complete cyclide which in Fig 3 was a uniform ring, the so-called 'anchor ring', is now thicker on one side than on the other

We are now going to see how, in imagination, we can divide a solid mass of material, such as that which lies on the microscope slide, into separate blocks, in each of which the substance is arranged on one or more sets of cyclides, while all the blocks can be fitted together so that the stratification runs continuously through the whole.

If two such conical regions are made to touch along a common generator, the cyclides in one region may be looked on as continuations of the cyclides in the other, though they come into contact only at the common generator. Any pyramidal space can be divided into cones, large ones in the centre, smaller cones partially filling up corners that are left, and still smaller cones filling up corners that are still left, and so on The pyramidal space can then be further sub-divided into strata of uniform thickness by sets of cyclides, one set to each cone, which all fit on to one another, and meet at right angles the straight lines drawn from the vertex to all the points on the polygon forming the base In each of the cones the vertex and the focus of the ellipse forming its base are the two terminal points on the hyperbola belonging to that cone. Since all the hyperbolæ lie on planes that are perpendicular to the bases of the cones, which bases are co-planar, and all pass through the vertex of the pyramid, the major axes of the ellipses all pass through the projection of the vertex on the basal plane

A solid block can be divided into two sets of pyramids, half of which have their bases on each one of two opposite faces and vertices on the other, together with certain wedge-like spaces. This is readily seen if we consider such a division as is indicated in Fig. 6, where the pyramids are, for simplicity, set on square bases; and it appears that besides the pyramids there are wedges or tetrahedra such as *IJPQ*. Pyramids and wedges account for the whole. Now the top and bottom edges of each wedge can be looked on as portions of a pair of focal conics, and the space inside the wedge can be divided by cyclides which meet the other four edges at right angles and therefore pass continuously into cyclides in the adjoining pyramids The top and bottom edges must have at least some small curvature If straight lines be drawn from every point on the upper edge to every point on the lower, they are all normal to the set of cyclides which divide the space inside the wedge into layers of uniform thickness Thus the whole of a solid block can be divided into uniformly thick contorted layers by Dupin cyclides belonging to a number of different sets which, however, fit on to each other perfectly

We have next to show that the optical effects are consistent with such an arrangement, and in fact establish its existence

In a solid crystal the direction of the axes is constant throughout In a liquid crystal this is not the case Fortunately for our convenience in solving the new problem, there is only one axial direction at each point, namely, that which is perpendicular to the layer, it coincides with the straight line passing through the point and also through the two focal conics We may divide into two parts the problem of the path of a ray through a liquid crystal Consider first the case when a continuous change in the direction of the crystal axis is taking place in the plane containing the path of the ray Let that plane be the plane of the paper and let the axes be directed towards the point *O* in Fig 7 Clearly a vibration which is perpendicular to the plane is always perpendicular to the axis wherever it is, and is never deflected But a vibration in the plane of the diagram is that of an 'extraordinary' ray and suffers continuous deflection Its path was calculated by Grandjean[8] who showed that it moves on the curve $r \cos n\alpha = a$, where r and α are polar coordinates, *O* being the pole, n is the ratio of the refractive index of the extraordinary to that of the ordinary ray, and a ($= OA$) is a constant If $n = 1$, the curve becomes a straight line, as it ought to do, since the substance would then behave as if isotropic, and a ray of light would go straight through. The curve in the figure has the two straight lines *OP* and *OQ* as asymptotes, and the angle $POQ = \pi/n$ An extraordinary ray approaching along a line originally parallel to *OP* but not directed at *O* is finally deflected along *OQ* At the beginning and the end it is very nearly an ordinary ray To sum up, ordinary rays consisting of vibrations normal to the diagram suffer no deflection, but extraordinary rays do

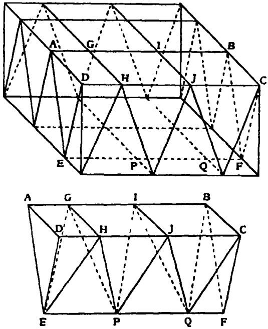

FIG 6 —The rectangular block is divided by saw-cuts into wedges the division being made in two ways, parallel to two of the edges of the block Below the block is shown one of the wedges obtained by cutting parallel to *AB* The second set of cuts, parallel to *AD*, divides this larger wedge into pyramids such as *P*(*GHIJ*) and smaller wedges such as *IJPQ*

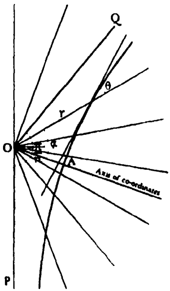

FIG 7 —The curved line shows the path of the extraordinary ray in a medium in which the axial direction at any point is directed towards *O* The axes and the path lie in one plane.

Next we consider a ray passing through a region where the direction of the axis is changing continuously but is always normal to the direction of the ray Such a structure may be termed a twisted or helicoidal structure In any plane which is normal to the ray, the direction of the axis is the same at every point but the direction changes continuously along the ray, as happens in a pack of cards to which a twist has been applied about an axis perpendicular to the plane of the cards

It is not to be expected that a polarised ray would maintain unchanged the rectilinear character of its vibration during its passage through such a medium , in fact, Maxwell's equations of the electro-magnetic field cannot be satisfied by so simple an assumption But if we try an elliptically polarised ray and suppose that the axes of the ellipse follow the twist, we find that the equations are satisfied for certain degrees of ellipticity and corresponding velocities We have therefore found the solution of our problem * A particular case is alone of importance to us here In cases with which we are dealing, the wave-length λ is very small compared to p, the pitch of the screw As Mauguin showed in the case of the nematic substances which we shall examine later, it is not possible to twist the medium so much as to make λ/p anything but a small fraction It appears that the ellipticities are then small, and the result can be expressed as follows :—

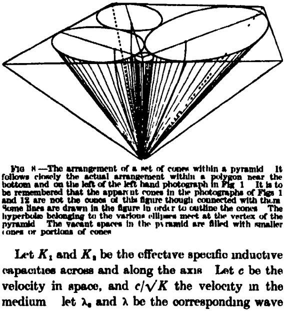

FIG 8 —The arrangement of a set of cones within a pyramid It follows closely the actual arrangement within a polygon near the bottom and on the left of the left hand photograph in Fig 1 It is to be remembered that the apparent cones in the photographs of Figs 1 and 12 are not the cones of this figure though connected with them Some lines are drawn in the figure in order to outline the cones The hyperbolæ belonging to the various ellipses meet at the vertex of the pyramid The vacant spaces in the pyramid are filled with smaller cones or portions of cones

Let K_1 and K_2 be the effective specific inductive capacities across and along the axis Let c be the velocity in space, and $c/\sqrt{K}$ the velocity in the medium let λ_0 and λ be the corresponding wave lengths Let a and b be the axes of the elliptical vibration Then *either* —

$K = K_1$ to the second order of small quantities and $b/a = 2\lambda K_1/p\ (K_1 - K_2) = 2\lambda_0\sqrt{K_1}/p\ (K_1 - K_2)$ *or* $K - K_2$ and $a/b = 2\lambda_0\sqrt{K_2}/p\ (K_2 - K_1)$

It appears therefore that in the twisted medium two elliptical vibrations can travel without change of form, each with its special velocity When the twist is small we may assume that incident light is resolved into two linear vibrations, the ellipticity being negligible These vibrations, however, follow the twist, so that the vibrations at any point are always along and perpendicular respectively to the crystal axis at that point If exactness were necessary, we should have to recognise that incident light is always resolved into two elliptic vibrations of different ellipticities travelling with different speeds For example, a polarised ray, in which the vibration is parallel to the crystal axis at the surface, is resolved into two elliptic vibrations which travel at different rates The major axis of the larger lies in the direction of the incident vibration, that of the smaller is perpendicular to it and is equal to the minor axis of the larger The two rotate in opposite directions At regularly spaced depths in the medium the two again combine into a linear vibration

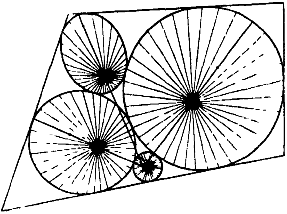

FIG 9 —This shows the base of the pyramid in Fig 8 and the axial directions radiating from every focus at the base of the hyperbolæ (see Fig 8) The axes of the ellipses all meet at a point which is the projection of the vertex of the pyramid upon the base

It is to be observed that this effect is practically independent of the wave-length The rate of rotation for all wave-lengths is that of the mechanical structure

Any axial direction can be brought into coincidence with any other axial direction by a rotation in the plane containing the direction of the ray combined with a rotation about the ray Thus we are able to say, as the result of the two cases considered, that the ordinary ray goes through the liquid crystal without any change in the direction of its path, no matter how the axis of the crystal alters its direction, provided that the latter alteration is continuous The direction of the vibration changes in such a way that it is always perpendicular to the axis of the crystal On the other hand, the extraordinary ray, though behaving like the ordinary ray in all other respects, continuously changes the direction of its path when there is any continuous change in the orientation of the crystal axis, which has a component in the plane containing the ray and the axis

---

* A short proof is given in *Proc Roy Inst*, [illegible], 90 , 1934

We can now proceed to examine the appearance of a smectic substance in the light of what we have just proved Let us consider the photographs in Fig 1 These are typical of the great variety of appearances presented by a thin layer of ethyl azoxybenzoate It is in the smectic state, the temperature being held between the limits 114°C and 120°C The microscope is focused on the upper surface of the layer and is viewed through an analysing Nicol There is no polariser We observe at once the assemblage of polygons each with its content of ellipses If we suppose that the substance is crumpled up into a combination of sets of cyclides as explained above, and also that these are grouped in cones, pyramids and wedges (see Figs 4, 5, 6, 8 and 9) then the arrangement of the optic axes in the surface of the layer will be as in Fig 9, with infinite possibility of variation in the number and sizes of the ellipses The molecules on the surface lie always on straight lines, which show the directions of the crystal axes at every point, and in each ellipse radiate from the focus to the circumference

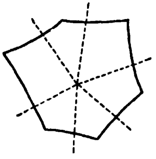

Fig 10—This shows the disposition of polygon edges in one face of the lower left hand portion of Fig 12 with respect to polygon edges in the other face

At every point the vibration in the ordinary ray as it emerges is perpendicular to the radius vector from the focus The original beam divides into two on entering the substance, as usual, but the extraordinary ray quickly goes astray If it gets through, its vibration is inclined to the radius vector, but its appearance is quite irregular On the other hand, the ordinary ray appears uniformly at all parts of the field and gives the clear picture which is seen in the microscope The analyser transmits vibrations parallel to its principal plane, and consequently each ellipse is crossed by a shadow which culminates at the focus The central line of the shadow is parallel to the principal plane of the Nicol It will be observed that when a polygon includes several ellipses, the major axes of those ellipses are all directed towards a single

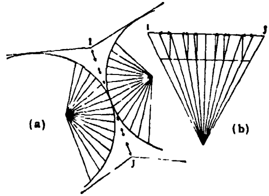

Fig 11 - This shows how the crystal axes in the edge of the wedge *IJ* are at right angles to the axes inside the ellipses where they touch the edge (*a*) About the middle of the edge the axes are often vertical This is very often the case in the left hand illustration in Fig 1 The light from below gets through on this line without being resolved, and is only half darkened by the analyser The section of *IJ* marked off by arrow heads represents the direction and relative values of the axial projection on *IJ* the manner of doing this is shown in (*b*)

point, which, as already explained, is the projection upon the polygon of the vertex of the pyramid standing on the polygon The vertex lies on the opposite face When the microscope is adjusted so that the lower face is in focus, it is found that the point on which the major axes of the ellipses converge melts into a point where a number of edges of polygons meet This is illustrated in Figs 10 and 12

The polygon edges of Fig 1 vary in shade, some being light and some dark It will be observed that the dark edges are more or less parallel to the middle line of the shadow in each polygon , and therefore also to the crystal axis along the edge This is readily understood when we remember that the side of the polygon is the top edge of a wedge Inside a wedge the axes run from every point on the top edge to every point on the bottom edge Along the top edge the projection of the axes is therefore parallel to the edge as shown in Fig 11 Somewhere in the edge, however, there is a point, unless the wedge is very skewed, where the axis is perpendicular to it, being the shortest distance between the top and bottom edges At this point the extraordinary becomes equivalent to the ordinary ray. There is no separation when the light enters the medium, and the analyser does not quench it entirely A black edge then shows a white spot in the middle

From the general and close agreement between theory and observation, we may surely conclude that the smectic substance is indeed arranged in strata which take the form of Dupin's cyclides There are, however, any number of other geometrical arrangements of sheets of uniform thickness There must be a reason why the cyclides are preferred, and it must be based on energy considerations A soap film stretched on a frame takes a form involving minimum energy, if the pressure is the same on both sides the total curvature is everywhere zero, and the edges comply with enforced boundary conditions In the same way the strata in the smectic state must also, while obeying boundary conditions, arrange themselves so that the potential energy is a minimum

Simplicity and symmetry imply less storage of energy than unnecessary complication and lack of symmetry Let us consider possible methods of arrangement in declining order of symmetry

If strata, originally plane and parallel to each other, are forced out of this arrangement, which is the simplest of all, they must tend to take the cylindrical form which comes next in simplicity. If the disturbing influences are complicated, the various attempts to adopt the cylindrical form must in some way be accommodated to each other A set of strata of even thickness, bent into cylindrical form, is so grouped round the axis of the cylinder that the normals to the strata at all points intersect the axis at right angles It is not possible, however, to divide a mass of the smectic substance into cylindrical groupings of this kind, the various groupings cannot be made conformable with each other

In the next order of simplicity the normals to the strata still meet in a line, but are inclined to it, forming cones of revolution, the vertices of which are points on the line, the inclination being constant in all directions radiating from any point on the line This is illustrated in various preceding figures, for example Fig 4 Each cone is symmetrical about its axis

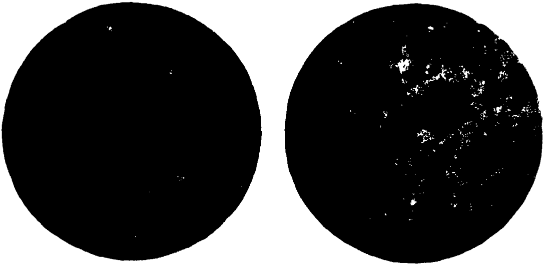

FIG 12 —Two photographs of the same portion of a smectic preparation, but in that on the right the upper surface is in focus, and in that on the left the lower In the lower left hand portion of the photograph on the right is a fairly regular six-sided polygon, of which the centre is occupied by an ellipse which is nearly a circle A number of smaller ellipses lie within the same polygon The axes of all those ellipses are directed to a point When the other surface is brought into focus this point is seen to be the meeting place of six polygon edges, as is shown by the illustration on the left This point is the vertex of a pyramid standing on the six sided polygon The six lines that meet in a point on one face are the upper edges of wedges of which the lower edges are the sides of the polygon on the other face They are separately at right angles to these lines because focal conics, however viewed, always seem to intersect at right angles See Fig 10

It is this arrangement which is adopted. Every normal to the strata is anchored on two lines which are focal conics Every boundary surface of the strata is as symmetrical as possible, being at right angles to series of cones of revolution, and the various sets of surfaces are conformable to each other as we have seen. The cyclides are the only surfaces which fulfil these conditions The geometry of the cyclide was considered by Clerk Maxwell[6], who pointed out that if the rays in a beam of light pass through two focal lines, the lines are necessarily parts of focal conics. The wave surfaces are equally spaced cyclides to which all the rays are normal

A useful list of substances which may exist in the smectic state is given by Friedel in the paper already referred to[2] The azoxybenzoate is often taken as typical, as it is easily made to show all the smectic characteristics

NEMATIC CRYSTALS

The second of the three classes of liquid crystals outlined by Friedel, was called by him 'nematic', from the singular appearance of mobile threads, either free in the interior of the substance or attached more or less to the bounding plates These have none of the focal conic structures of the smectic substances, having in fact no stratification They possess optical properties, however, and therefore some degree of molecular arrangement What that arrangement is may well be inferred from a recent determination of the solid crystal structure by Bernal and Crowfoot[7] *Para*-azoxyanisole and *para*-azoxyphenetole are typical nematic substances

$$\mathrm{CH_3-O-C_6H_4-\underset{O}{N-N}-C_6H_4-O\ CH_3}$$

Para-azoxyanisole

Solid – 116° – nematic – 133° – liquid

$$\mathrm{C_2H_5-O-C_6H_4-\underset{O}{N-N}-C_6H_4-O-C_2H_5}$$

Para-azoxyphenetole

Solid – 135° – nematic – 165° – liquid

X-ray analysis shows that the molecules in the solid lie parallel to one another, but cannot be clearly separated into layers They interleave one another, or, to use the description by the authors referred to, they are imbricated. Certain indications found on the X-ray photographs show also that the degree of interpenetration is not sharply defined but is variable about an average value. Since the change from solid to the 'liquid crystal' form is so easy, there cannot be much variation in arrangement or bindings, and the natural inference is that, even more in the latter than in the former phase, the interpenetration lengthways is variable and easily effected We should therefore conceive of the substance as owing its mobility to the facility with which the molecules can be drawn past each other, while retaining a strong tendency to acquire or retain a parallelism between the long dimensions of the molecules and the direction of drawing

Another striking characteristic of the nematic state is the tendency for the molecules to be attached sideways to the slide or the coverslip If once a solid crystal has formed between the two glass surfaces, it is difficult to remove all traces of its having done so The substance may be completely melted and allowed to return to the nematic state, whereupon it will recrystallise more or less according to the same plan as before The melting does not remove all the molecules adhering sideways to the glass, and enough remain to redirect the molecules in their former orientation in each separate part of the preparation In the microscope, when the Nicols are crossed, the appearance is that of a map in which the different countries are 'differently tinted, because the general direction of the molecules in each part is peculiar to that part In each part the direction may be the same right through the preparation from one glass surface to the other, especially if the layer is thin. If one or both of the Nicols are rotated, the alternations of light and dark are the same as if the preparation were a section of a uniaxial real crystal Yet the substance is liquid (Friedel, *loc cit*) If particles of dust or other intrusions wander through it they move freely, while the optical effects are unchanged The orientations of the molecules are governed by those on the surface, and even if there is a stream flowing, they do not diverge from the common orientation of the section in which they are But, if they move into another section, they change the old orientation for a new one

Suppose now that the cover slip is moved, either by translation or by rotation with respect to the slide In many places it must consequently happen that the orientation of the molecules on the top face is different from the corresponding orientation on the face below The angle between them is α, let us say It then appears that there is a gradual transition from one orientation to the other on the way through ; the substance assumes a helicoidal or twisted arrangement If a polariser is set parallel to the molecules on the lower surface, the analyser, in order to obtain extinction, must be set, not in the perpendicular direction but at an angle α thereto We have a straightforward example of the twisted medium which we have already considered Both ordinary and extraordinary rays follow the screw-like arrangement of the structure, the vibration in the one remaining always normal to the molecule, and therefore to the optic axis, while the other vibration is always parallel to it In this case there is no deflection of the extraordinary ray

The substance in the nematic state does not always assume the simple arrangement in plane sheets, in which the axes are parallel to the surface If it is cooled quickly from the amorphous phase, or if less care is taken in the preparation of the glass plates, it becomes full of complicated vortices and intertwinings Among these are the fine lines or threads from which the phase derives its name, they are especially obvious where the preparation is thick The threads are lines of discontinuity close to it There must then be a deflection of the ordinary ray because the thread is visible It may be that there is actually a hollow cylinder—perhaps vacuous—providing a reflecting surface, or it may be that the excessive strain of the medium close to the thread actually alters the refractive index of the ordinary ray

The latter explanation would involve the introduction of a principle not used hitherto in these considerations It has been sufficient, so far, to ascribe the optical effects to geometrical arrangement The extraordinary ray, on the other hand, may be deflected, since it passes through a region in which the crystal axis is continuously changing its direction in the plane containing axis and ray giving rise to optical effects, in accordance with the calculations made above A thread might be a line which is the meeting place of crystal axes at all points of its length, as in the smectic case There is now no necessity, however, for the line to be part of an ellipse or hyperbola, because it has no companion with which to form a pair of focal conics Or again, it might be a line round which the medium is circulating, corresponding to a vortex ring, which is either complete or anchored at two ends The molecules and the optic axes are then tangential to circles having the line as axis Sometimes a line marks the boundary between two portions in which the axial directions are different

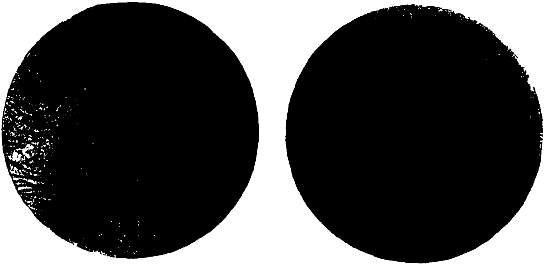

FIG 13 —The two photographs show the same substance, para-azoxyphenetole in the nematic phase, at two moments separated by as short an interval as possible The only difference is that the position of the analyser in one case is approximately at right angles to its position in the other No polariser The clearer portion of each photograph is seen by ordinary rays, and the other by extraordinary rays

In these cases, the ordinary ray is not deflected as it passes by the thread, unless it passes very

From this point of view we see at once the explanation of a very remarkable and characteristic appearance of the nematic substances, which is illustrated in the photographs of Fig 13 These are photographs of the same preparation, taken one after the other as quickly as possible so as to avoid changes due to the continuous movement of the liquid The light entering from below is not polarised but passes through an analyser after crossing the preparation The obvious difference between the two photographs is due to the fact that the analyser was rotated through about 90° between the two exposures The threads that look narrow and clear in one photograph are distorted in the other, a close comparison will show that otherwise the two photographs are identical

The remarkable feature which demands explanation is the fact that all the threads in one part of the picture should be clear simultaneously, while in another part they are all blurred We remember, however, that there can be a skin or pellicle, to use Friedel's term, in contact with the glass surface, in other words, the previous existence of a solid crystal there has left molecules on the glass which all point the same way, like a flock of birds on the ground which all head up into the wind This sets the orientation of other molecules in the near neighbourhood of the glass, and though the molecules may be orientated in all kinds of ways between the top and the bottom of the preparation, the change is never discontinuous except in the thread' itself, even then the continuity passes round the thread, if not through it Consequently the ordinary rays emerge with their vibrations perpendicular to the axis of the pellicle at the point of emergence, though when the rays passed by the thread, the vibrations were all parallel or perpendicular to the thread, according to the view which we take of the nature of the thread The vibrations of the extraordinary rays are all perpendicular to those of the ordinary The analysing Nicol can therefore be set so as to extinguish all the extraordinary rays and transmit only the ordinary, so that the threads are seen clearly If the Nicol is set so that the view is obtained by means of the extraordinary rays, the images are blurred because those rays are deflected out of their course by going near the threads

The whole effect depends on the compelling power of the pellicle, setting an arrangement at the surface to which the internal arrangement, whatever it may be at a distance from the surface, must gradually conform as the distance from the surface diminishes The vibrations have been orientated in a different direction at each point of the tortuous thread, but have all been pulled into one direction when they emerge In Fig 13 there are two regions, in one of them the molecular direction in the surface happens to be more or less at right angles to the direction in the other so that when one part, seen by ordinary rays, is clear, the other, seen by extraordinary rays, is confused The optical effects of nematic threads have been studied by H Zocher and his colleagues[8]

When the *para*-azoxyanisole is cooling down from the liquid, the first appearance of a change of phase is the formation of separate groups of molecules, which between crossed Nicols give the effect illustrated in Fig 14 Each group shows, besides finer details, a cross, the arms of which are parallel to the principal planes of the Nicols A similar effect may be observed in certain solids, such as strontium carbonate or salicin, and occasionally lavas and glasses, and in organic substances such as cholesteryl acetate It is an indication that in each group there is a nuclear point from which the axes of minute crystals radiate uniformly in all directions In two of those directions, mutually at right angles, the axes of the crystals are parallel respectively to the principal planes of the crossed Nicols If the preparation is rotated with respect to the Nicols, the cross does not move The group is therefore independent of any pellicles, it is floating freely in the middle of isotropic liquid The molecules either radiate from the nucleus in the centre, or are arranged along concentric circles as if there were a vortex Either arrangement gives the cross On one side of Fig 14, the groups are coalescing and are attaching themselves to the glass above and below The connexions are irregular but there are traces of the original simple arrangements of the groups On the border between the liquid crystal phase are larger groups formed by the coalescence of smaller groups

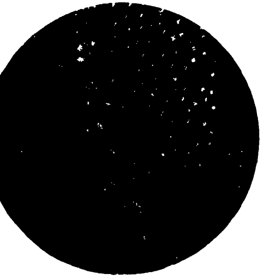

FIG 14 —*Para* azoxyanisole cooling between crossed Nicols On the left the nematic state is advancing Small drops are forming in the liquid on the right The arms of the crosses are parallel to the principal planes of the Nicols The larger drops are formed by coalescence of the smaller

CHOLESTERIC CRYSTALS

The third class of liquid crystals has been termed by Friedel the cholesteric In some ways its properties resemble those of the smectic and nematic classes But we meet here with a new effect, a brilliant coloration of which the causes and laws have never been fully explained

We may take as an example

$$C_6H_5-CH=CH-CO-O-C_{27}H_{45}$$

Cholesteryl cinnamate

Solid – 156° -- cholesteric – 197° – liquid

When this substance is allowed to cool down from the liquid phase, it presents at first a confused appearance of a focal conic structure But a slight mechanical disturbance causes it to assume a form in which it reflects brilliant colours like those of a peacock's feather The colour depends on the temperature, being vivid green at the higher temperatures and golden-bronze at the lower But the most remarkable effect is that the reflected or, more correctly speaking, scattered light, is circularly polarised If the incident light is circularly polarised, it is reflected if the circulation is represented by a right-handed screw, and transmitted if the screw is left-handed In the case of some other cholesteric substances this is reversed More remarkable still is the fact that the scattered light is right-handed, like the absorbed light to which it is due In all other known cases of the reflection of circularly polarised light the sense of the rotation is reversed.

These substances, when in their characteristic state, are optically active to an extraordinary degree, represented sometimes by as much as a whole turn in the hundredth of a millimetre.

This short account of the chief properties of 'liquid crystals' is very far from complete Nothing has been said of the influence of electrical and magnetic fields on molecular arrangement, which is strong in the case of substances in the nematic phase but absent in the smectic, except during the process of cooling from the liquid Nor has reference been made to the peculiar facility with which the molecules of liquid crystals dispose themselves in particular directions on fresh cleavage faces of solid crystals Nor have the viscosity effects been described In spite of these omissions, the account may help as an introduction to the extensive literature of the subject, the more so because the accumulated observations are scattered over many scientific journals, and because also the various workers are far from agreement as to their interpretations

Progress in Wool Research

A PAMPHLET recently issued by the Wool Industries Research Association summarises, under the title "Scientific Research applied to the Wool Industries", a number of the practical results of the work These include the invention of durable sheep-marking fluids *completely removable in subsequent processing* and leaving no traces in the finished fabric The investigations on the recovery of wool grease from scouring liquors have contributed largely to the development of three processes in use at Bradford and elsewhere, while those on wool scouring, for example, have made possible the actual detection and commercial control of variable alkalinity by means of indicator cloth. The discovery of the chemical changes responsible for discoloration in carbonising have enabled adequate precautions for prevention to be taken Improved 'ionised' oils have been developed for the lubrication of wool Fundamental issues underlying the woollen spinning process have been elucidated, a new principle in roller drafting has been discovered for use in the spinning of dry combed rovings and a general relation developed between count, twist and strength for single worsted yarns. Causes of deterioration of spinning ability of dyed wool have been ascertained and of damage in fabrics through lead staining in weaving. Mothproofing and preservation against moulds and mildew have been important fields of work, and in these and in many other ways the application of quantitative measures has assisted in the control and efficiency of the numerous processes with which the wool industry is concerned

Association of Scientific Workers

THE annual report of the Executive Committee of the Association of Scientific Workers presented to the Council on February 24 refers to the formation of a National Parliamentary Science Committee as an outcome of negotiations with the British Science Guild as the outstanding special work of the year. The support of twelve leading institutions has been obtained, and the committee includes Sir James Henderson, Prof. Miles Walker, Prof Blackman, with Commander Bernacchi as chairman, and Mr. A. Howard and Mr. H J. W. Stone as joint honorary secretaries In consequence, the Parliamentary Committee of the British Science Guild and of the Association have been disbanded. The compilation of a "Handbook of Extra-University Research in Pure and Applied Science", giving data concerning commercial, endowed and private research laboratories, has been completed and negotiations for publication are in progress. It is believed that the handbook will serve as an advertisement of British research activities and of the interest taken by British industrialists in maintaining the highest efficiency in factories. The book may become a standard work of reference alongside the "Universities Yearbook" and the "Year-Book of Scientific and Learned Societies".

THE Association has been active in combating the evil of bogus degrees and has been in negotiation with the universities to secure their support of successive Bills introduced in the House of Lords by Lord Jessel to deal with this evil. The Association collected a considerable amount of information regarding the granting of degrees by five different British 'degree-mongers' but has so far been unable to induce the universities to withdraw their opposition at the third reading of the Bills The finance of the research associations has received attention and is being considered by a joint Committee of the Association and the British Science Guild. The production of "Science in Parliament" has continued and a memorandum has also been prepared on the relation of the unification of national transport, the construction of ship-canals across Britain, the reconstruction of derelict canals and land-drainage The report concludes by directing attention to the resolution passed that members should seek to assist towards a better adjustment between scientific advances and social progress

Absence of Winter Rains in England and Wales

THE Director of the Meteorological Office, Air Ministry, states that the rainfall over England and Wales has been less than the average for nine out of the last eleven months. August, November, December and February stand out conspicuously for their dryness In October and January the fall was slightly above the average but there is not a single month of large excess. Taking the period as a whole, the rainfall was everywhere less than the average except along a strip of the east coast from Newcastle to Hull and again near Yarmouth There were two areas in which the deficiency was particularly large, the fall amounting only to about two thirds of the average The first of these is bounded roughly by the counties Breconshire, Bedfordshire, Somersetshire and Surrey , the second includes the Cheshire plain and the coastal strip of Lancashire. The absence of the winter rains on which we rely to such a large extent for keeping up our water supplies is remarkable The rainfall for the four months November–February was less than half the average over a great part of the country south of a line from Aberystwyth to Yarmouth, and there are regions of similar deficiency to the west of the Pennines and in south Lancashire In January, heavy falls amounting to about 20 inches fell in Snowdonia and the English Lake District, but less than two inches were measured over the eastern half of England, and less than an inch in the neighbourhood of Middlesbrough and the Wash The deficiency for February was also marked. Totals of more than an inch were confined to Snowdonia, the neighbourhood of Borrowdale and parts of the north-east coast Locally, for example at Patching Farm near Littlehampton, there was *no measurable rainfall for the whole of the month*, a very unusual occurrence The partial failure of the winter rain has been the most severe since the memorable winter of 1879–80, which, however, followed a wet summer, whereas the summer of 1933 was dry

Award to Dr. F. W. Pennell

THE first award of the George W Carpenter fund for encouragement of scientific research was made on

February 20 by the Academy of Natural Sciences of Philadelphia to Dr Francis W. Pennell, curator of botany in the Academy, for his work and study on the snapdragon family (Scrophulariaceæ) of eastern North America. In presenting the 250 dollars honorarium at the annual meeting, the president announced that this fund also will permit publication of Dr Pennell's book on the subject The George W Carpenter fund is a bequest from the late Mrs Ellen D C Bennett, in memory of her father, one of the Academy's earliest members, who served as treasurer from 1826 until his death in 1860 Dr Pennell was appointed curator of botany at the Academy in 1921, and under his direction this Department has become one of the largest of its kind in the United States, containing at the present time more than 600,000 specimens of plants and flowers from all parts of the world Among these are some of the oldest and most valuable of American collections

Ray Society

At the annual general meeting of the Ray Society held on March 13, the following officers were re-elected: *President*, Sir Sidney Harmer, *Treasurer*, Sir David Prain, *Secretary*, Dr W T Calman Mr J M Offord was elected a vice-president in succession to the late Canon G R Bullock Webster, and Mr R. S W Sears, Mr M A C Hinton and Mr A G Lowndes were elected new members of Council The Council's report directed attention to the decline in the receipts from all the regular sources of the Society's income, and stated that unless further support for the Society is obtained, a regrettable curtailment of publications may soon become necessary It was stated that the plates for the second volume of Prof T A. Stephenson's "British Sea Anemones" are being engraved, and it is hoped that the volume will soon be in the press The Council reported with gratitude the receipt of a donation of £30 towards the cost of this volume from Miss Teresa Gosse, the grand-daughter of Philip Henry Gosse, author of the "Actinologia Britannica" (1860)

Soviet Stamps in Commemoration of Mendeléeff

THE Soviet postal authorities have issued a series of new postage stamps to commemorate the centenary this year of the birth of Mendeléeff The new issues are of five, ten, fifteen and twenty kopek denominations The five and the twenty kopek denominations bear a design of the Mendeléeff monument against a background of his table of the periodic system of elements, the ten and fifteen kopek denominations bear a portrait of Mendeléeff, also against a background of the table of the periodic system of elements All the stamps bear the commemoration date 1834–1934

Vital Statistics for the Year 1933

THE Registrar-General has issued a provisional statement of the figures for birth-rate, death-rate and infant mortality in Great Britain during the year 1933 For England and Wales, the live births and the deaths were respectively 14 4 and 12 3 per 1,000 resident population, and the deaths of infants less than 1 year old, 64 per 1,000 registered live births For the fifth year in succession the birth rate was the lowest on record, being 0 9 per thousand below that of 1932, and 1 4 below that of 1931 The death rate was 0 3 above that for 1932 and is the same as that for 1931 The infant mortality rate was 1 per 1,000 below that for 1932, and with the exception of the year 1930 (60) is the lowest on record

Announcements

AT the annual general meeting of the Physical Society, held on March 16, the following officers were elected *President*, The Right Hon Lord Rayleigh; *Vice-President*, Dr D Owen, *Secretaries*, Dr Allan Ferguson (*Papers*), Dr Ezer Griffiths (*Business*); *Foreign Secretary*, Prof O W Richardson, *Treasurer*, Mr R S Whipple, *Librarian*, Dr J H Brinkworth, *New Members of Council*, Mr H H Emsley, Prof H R Robinson

THE Institute of Physics has put forward a scheme for the training and certificating of laboratory and technical assistants in physics, and proposes in due course to set up an appointments register Candidates for the Institute's certificates must attend approved courses of instruction and pass examinations in accordance with the regulations issued It is understood that evening class courses for the Institute's certificates will be commenced in September next in London

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —Engineers at the Fuel Research Station, East Greenwich—Establishment Officer, Department of Scientific and Industrial Research, 16 Old Queen Street, S W 1 (March 26) An assistant in the Admiralty Technical Pool for duty at the Admiralty Compass Department —Secretary of the Admiralty (C E Branch), London, S W.1 (March 28). A veterinary officer under the Devon County Council—County Medical Officer, 4 Barnfield Crescent, Exeter (March 29) Two junior assistant engineers on the Manchester Corporation—City Engineer (March 30) Engineer and manager of the Weymouth Waterworks Company—Chairman (April 3). Water engineer and manager and gas examiner to the County Borough of Swansea—Town Clerk, Guildhall, Swansea (April 7) Principal of the County Technical College and School of Art, Newark —Clerk to the Governors (April 10) A demonstrator in zoology at University College, Nottingham—Registrar (April 11). A demonstrator in the Department of Inorganic and Physical Chemistry at Bedford College for Women, Regent's Park, N W 1—The Secretary (April 21) Two technical assistants (A. 587/8) and a draughtsman (A 589) at the Royal Aircraft Establishment, Farnborough, Hants—Chief Superintendent, quoting reference number above. Two resident staff tutors for adult education, University of Birmingham—Director of Extra-Mural Studies (April 23) University professor of anatomy at St. Thomas's Hospital Medical School, London—Academic Registrar, University of London, S.W.7 (May 16)

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Supraconductivity of Films of Tin

EXPERIMENTS on the relation of high frequency currents to the phenomenon of superconductivity led to work at Toronto with films of superconducting metals. The films (of tin) were produced by 'tinning' the surface of fine wires which themselves were not superconducting. In the early experiments a coating of tin 2 × 10⁻⁴ cm in thickness was 'wiped' on constantan wire of 0·016 cm diameter. In this way one obtains the equivalent of a thin cylinder of superconducting metal, and the resistance of the whole becomes zero below the transition temperature of the superconducting element used[1].

With the intention of studying further the effect of high frequency currents, samples of such coated wires were plated with other metals—for example, copper and nickel—which are not superconductors; an example of such a combination is constantan covered with tin and then plated with copper. The diameters of the wires forming the core were as follows: for constantan 0·056 cm, for copper 0·040 cm and for nickel 0·045 cm.

Preliminary experiments were carried out on these samples to confirm their reaction with respect to direct currents—the ordinary superconductivity test—and it was found that thin films of tin cease to show superconductivity when these films are themselves plated over with a film of a non-superconducting metal, for example, copper or nickel. This surprising result shows itself only with thin films, but a number of repetitions of the experiments renders the results unmistakable. The accompanying table shows the nature of the phenomenon; so far, only the superconductor tin has been tested in this way.

No	Sample	Thickness of Tin Film (cm × 10^{-6})	Thickness of outer layer (cm × 10^{-6})	Superconductive Action, direct current of 200 ma
1a	Constantan-Tin	10	0	Transition point 3·69°K
1b	Constantan-Tin-Copper	10	100	Not superconducting at 2°K
2a	Copper-Tin	9	0	Transition point 3·58°K
2b	Copper-Tin-Copper	9	100	Not superconducting at 2°K
3a	Nickel-Tin	9	0	Transition point 3·42°K
3b	Nickel-Tin-Copper	9	100	Not superconducting at 2°K
4	Constantan-Tin	6·8	0	Transition point 3·49°K
5	Constantan-Tin	2	0	Transition point 2·48°K
6	Constantan-Tin-Copper	18	40	Not superconducting at 2°K
7	Constantan-Tin-Copper	4	20	Not superconducting at 2°K
8	Constantan-Tin-Nickel	15	30	Not superconducting at 2°K
9	Constantan-Tin (wiped)	90	0	Transition point 3·68°K
9a	Constantan-Tin-Copper	90	80	Transition point 3·44°K
10	Constantan-Tin (electro-plated)	200	0	Transition point 3·76°K
10a	Constantan-Tin-Copper	200	80	Transition point 3·73°K
11	Tin Wire	diameter	0·065	Transition point 3·77°K

It is seen that as the film of tin increases in thickness, a point is reached at which the superconducting property of the tin film is not lost by surface plating. This phenomenon will undoubtedly be of importance in framing a satisfactory theory of superconductivity—a consideration of utmost importance in dealing with metallic conduction. This work is being carried on by J. O. Wilhelm and A. D. Misener.

Persistent Currents in Supraconductors

UNTIL recently it was generally assumed that it was possible to predict, by the ordinary electromagnetic equations, the persistent current produced in a supraconductor cooled below the transition point in a constant external magnetic field after the field was switched off. Thus H. A. Lorentz[1] calculated the current induced in a supraconducting sphere, that is, the effective magnetic dipole when an external magnetic field is established.

According to results recently published by Meissner and Ochsenfeld[2], the matter is not so simple as might at first sight appear. Instead of the lines of force being 'frozen in' as had been previously assumed would happen when a supraconductor was cooled below the transition point in a magnetic field, it appeared that the field increased in the neighbourhood of the supraconductor, which behaved as a body of zero permeability. If this were so, the flux of induction in the supraconductor should be zero and one might expect, in contradistinction to the old view, that no persistent current or effective induced dipole would be produced by switching off the external field.

The following experiments seem to show that although supraconductors do not conform to the older theory, neither do they behave as though they had zero permeability.

(1) A solid tin sphere of 1·5 cm. radius was cooled from 4·2° K. to 2·5° K. (the liquid helium was produced in a liquefaction apparatus utilising the expansion method of Simon) in a field of 70 gauss. When the field was switched off, the magnetic moment of the sphere was observed with a test coil. Its magnitude was about one sixth of that calculated according to the Lorentz equation.

The magnetic moment remained almost constant whilst the temperature of the sphere rose from 2·5° to 2·9°; with a further rise in temperature it decreased steadily, becoming zero at 3·7°, the normal transition point of tin. Plotting the magnetic moment against the temperature, one obtains a curve of similar shape to that found for the magnetic threshold values.

(2) The same sphere was cooled to 2·5° without any external magnetic field, a field of 230 gauss (higher than the threshold value at this temperature) was switched on and immediately switched off. The magnetic moment thus produced in the sphere at 2·5° was 8 per cent greater than that produced in the previous experiment using 70 gauss, but as the temperature rose it decreased and at 2·9° it reached the same value as the magnetic moment at this temperature in the previous experiment. From 2·9° to 4° the curve coincided with that found in experiment (1).

(3) Similar experiments to those described above

were carried out with a hollow tin sphere of the same radius, the spherical space in the middle being equal in volume to one half the volume of the sphere. The magnetic moments produced in the hollow sphere were two to three times greater than those obtained with the solid sphere

In all these experiments the magnetic field was produced by a cylindrical coil in the middle of which the sphere was placed, all iron being excluded. Although the field near the sphere was thus fairly homogeneous, we think it possible that the observed phenomena may be influenced by slight inhomogeneities of the external field. In a completely homogeneous field it would seem possible that the method of cooling might affect the results. In order to test this, we cooled the spheres from the poles and also from the equator This did not seem to make any difference, the magnetic moment observed being of the same order of magnitude in either case.

As a result of these experiments, it seems certain that the effective permeability of substances when they become supraconducting decreases, as observed by Meissner and Ochsenfeld On the other hand, it appears clear that under our experimental conditions the permeability does not vanish entirely, as might be expected in view of the almost infinite conductivity, or if it does vanish, it only does so in certain regions and not throughout the whole volume of the supraconductor.

In conclusion, we would like to express our thanks to Mr T C. Keeley for his advice and assistance in various phases of the work

Some Thermal Properties of Condensed Helium

IN the following communication we give the results of some preliminary measurements with condensed helium:

1. The heat of fusion is 6·75 cal./gm.-atom at 4·0° and 5·1 cal. at 3·4°.
2. The density of solid helium in equilibrium with the liquid phase is 0·23 at 4·0° and 0·22 at 3·6°.
3. The density and compressibility of liquid helium have been measured at 2·4° and 4·5° They are in good agreement with the data recently published by Keesom[1] We would add only that the compressibility still falls appreciably with higher pressure
4. The compressibility of solid helium could be measured roughly, the result being about $1·5 \times 10^{-3}$ reciprocal atm at 3·7° and 115 atm.
5. The specific heat of solid helium was determined between 2·7° and 3·7° at a density of 0·23. C_v agrees well in this region with a Debye function for $\Theta = 32·5°$. This small value (the smallest hitherto observed), which we find in spite of the small atomic weight, is another consequence of the very weak interatomic forces. From $\Theta = 32·5°$ follows a zero point energy of 73 cal./gm.-atom, compared with a thermal energy of only 1 cal. at 4°. We may mention that this value agrees well with the deviation from Trouton's rule if we attribute this to the zero point energy[2].
6. Measurements of adiabatic expansion were carried out in connexion with a proposed procedure[3] for lowering temperatures by changing the volume of condensed helium. The coefficient $\gamma = -(\partial \ln T/\partial \ln v)_S$ was measured for the liquid phase as a function of temperature and pressure We may mention as an example, that starting at 4·6° and 130 atm., 2·4° is reached by expanding to the vapour pressure Expansion experiments with solid helium have not yet been carried out, nor accurate experiments on the more easily made adiabatic expansion starting from the solid at equilibrium pressure We have done only one preliminary experiment starting from partly solidified helium at 4°, and this showed an appreciable increase in the cooling effect as compared with the effect obtained with only liquid present (The data given above, however, enable us to calculate these cooling effects Starting with solidified helium at the equilibrium pressure at 4°, one should reach a temperature of 1·4° by expanding to the vapour pressure As according to the measurements of Keesom[4] on the thermal expansion an adiabatic expansion of the liquid below the λ-point should lead to a temperature rise, a lower temperature will be obtained by expanding only until the substance is just melted Keesom's entropy diagram of the liquid[5] shows that in this case a temperature 0·15° lower should be reached Definite predictions of the cooling effects when starting at lower temperatures cannot be given yet.)
7. The knowledge of the specific heat of the solid phase enables us to fix the zero point of entropy according to Nernst's Theorem. The absolute value of the entropy of the liquid can now be calculated using the values of the heat of fusion, the data of adiabatic expansion and the specific heats Connexion can be made through the known values of vapour pressures and heats of evaporation with the theoretical value of the entropy of the gas, putting the statistical weight equal to unity according to the spectroscopic observations We find good agreement, the resulting chemical constant being −0·62 compared with the theoretical value −0·68

The investigations were carried out in 1932 in Breslau Their continuation is being undertaken in the Clarendon Laboratory

A Mercury-Sealed Water-Cooled Rotating X-Ray Target

INSPIRED by the magnificent X-ray tube with spinning target designed by Müller[1] and now in operation at the Davy Faraday Laboratory of the Royal Institution, we have considered the feasibility of completely sealing off the rotating anode by means of mercury after the manner of the classical Torricelli experiment.

At first sight such a proposition seems absurd for an X-ray tube containing a glowing filament, but we have overcome the difficulty very simply by covering the inner mercury meniscus with a layer of Apiezon high-vacuum oil Fig 1, which is self-explanatory, shows diagrammatically a tube which we have constructed and proved to work, not as yet, owing to lack of resources, with the large currents Muller has used, it is true, but still under sufficiently stringent conditions to demonstrate the essential soundness of the method Even with ordinary steel steam tubes, unpolished on their inner surfaces, the vacuum was found to hold exceedingly well. The annular space containing the mercury was about ¼ in wide, and the pump used was a two- or three-stage oil diffusion pump. Incidentally, these experiments show that mercury gauges can safely be used in combination with such oil diffusion pumps, if the precaution is taken of covering the mercury meniscus with a layer of high-vacuum oil

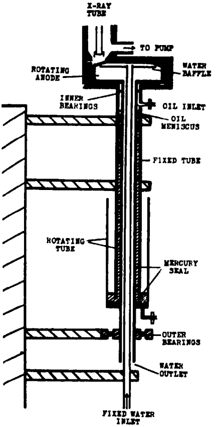

FIG 1.

The expenses of this investigation were met by grants from the Government Grant Committee of the Royal Society, and the Commissioners of the 1851 Exhibition. For the mechanical workmanship we are indebted to Mr. A. Robinson of this department.

Radio-Geological Survey of Czechoslovakia

BOHEMIA is an excellent region for radio-geological investigation In the first place, we have the ore region of Jáchymov (Joachimsthal), where pitchblende is found. However, in the Krkonoše (Riesen Gebirge) and in the Jizera Mts, where there are no deposits of pitch-blende, strong radioactive springs (containing up to 200 Mache units) occur very frequently along faults, contacts, etc This district has been investigated by us radio-geologically in the same manner as that in which Gensor investigated the German portion of the Krušné Hory (Erz Gebirge)[1]

During the last three years, we have gathered together much material by various experimental methods. Chiefly, so far as was possible, the radioactivity of springs in the whole area of the Krkonoše was measured systematically. The content of radium emanation was measured at different seasons of the year, the springs and their radioactivity were then marked on maps, so that radiological maps of the terrain might be formed, as suggested by Vernadsky, These maps will be made still more complete by the investigation of the soil-atmosphere In highly active springs the flow of the water, found to be inversely proportional to its radioactivity, was measured and its dependence on meteorological factors determined The springs are, therefore, regarded as superficial Further, the amount of radium was ascertained in the water of the strongest springs (of the order of 10^{-11} gm of radium element to 1 litre of water), and its quality by Elster Geitel's mesothorium method We have made also precise chemical analyses of the strongest springs

At the same time, analyses of the rocks in the neighbourhood of the springs have been made with regard to their contents in radium elements A simplification of Joly's method has been used, in which the rock is melted in the electric furnace, in cheap iron pans[2]. Likewise, rock sections were studied from the mineralogical point of view Correlation between geological structure and the analyses of waters and rocks were studied It was proved, for example, that at Žaly (Heidelberg on Benecko) waters became radioactive on contact with phyllite (radium content, $8 \cdot 3 \times 10^{-12}$ per gm) and orthogneisses (radium content, $4-7 \times 10^{-12}$ per gm) The total length of contacts is so great that the amount of emanation in the springs of this district (100 Mache units) can be easily explained by the absorption of emanation by the water along this quite superficial contact

A report of the first part of these investigations in the area of the Krkonoše will be published soon. We have dealt also with a large amount of material, especially from radiological investigations of the rocks from the ore region of Jáchymov and of rocks of organic origin from Bohemia and from Slovakia. This material will be completed and gradually published The aim of the work is a radio-geological survey of the whole of Czechoslovakia

Origin of the Angiosperms

THE cyto-genetic work of the past decade has built up an increasingly impressive body of data demonstrating the evolutionary importance of fertile, true-breeding hybrids originating through doubling of the chromosome number A considerable number of such hybrids (variously termed amphidiploids, summation hybrids, allopolyploids) have originated under observation Particularly interesting from the evolutionary point of view are Muntzing's 'synthetic' *Galeopsis Tetrahit*, produced from *G. pubescens* and *G speciosa*[1], and Karpechenko's *Raphano-Brassica*, an intergeneric hybrid which, were it found in Nature, would be considered a new genus[2]

An enormous body of indirect evidence suggests that similar 'summation hybrids' have occurred frequently in the development of many of the families of the angiosperms There is even some evidence for the reticulate origin of groups larger than the genus. For the sub-family Pomoideæ, the genetical and cytological evidence for the reticulate origin of that whole group from a cross or crosses between other members of the Rosaceæ is so strong that such a theory was put forward independently by Darlington and Moffett[3] and by Sax[4].

The following suggestion for a reticulate origin of the Magnoliales, though admittedly highly speculative, *is therefore not without precedent* Whitaker's recent work[5] has shown that these peculiar odds and ends do indeed form a natural order, though the affinity of certain of the genera (as, for example, *Cercidiphyllum* and *Trochodendron*) had previously been questioned He has suggested that the genera *Tetracentron*, *Drimys*, *Cercidiphyllum*, *Trochodendron*, *Magnolia* and *Liriodendron*, agreeing as they do in nodal anatomy and chromosome number, should be placed together in one group It is noteworthy that this group includes several genera which have been repeatedly considered as possibly transitional between the gymnosperms and the angiosperms, some of them being so placed by reason of their floral anatomy and others because of the structure of their wood Cytologically, the group is unusual by reason of its basic chromosome number of 19, which is seldom met with among the other families of the flowering plants

May it be possible that the Magnoliales originated from wide crosses between different groups of gymnosperms ? So far as chromosome numbers are concerned, the data are certainly suggestive. On the basis of chromosome number, the Gymnospermæ can be divided into two groups[6] To the larger group belong the Ginkgoales, Cycadales and Coniferales with base numbers of 12 and 11 To the smaller group belong the Gnetales, two genera of which have been found to possess base numbers of 7 *It will be seen that the chromosome number for the* Magnoliales is exactly what would obtain were a sterile cross between these two groups to double its chromosome number.

An *origin for the flowering plants* has usually been sought either among the Gnetales or the Cycadales. The evidence from chromosome numbers would suggest, *as one possibility*, that relatives of each might have contributed, reticulately, to the origin of the Magnoliales. For the immediate present, the cytologist can do no more than raise the question, "May the angiosperms have originated, in part at least, from crosses between some of the simpler members of the seven chromosomed and twelve chromosomed gymnosperms ?" The morphological evidence has not, I believe, been examined from this point of view. It would be interesting to know how far it supports such a hypothesis

Chemotropic Response of a Chironomid Fly (*Forcipomyia* sp.) to Petroleum Oils

SINCE the discovery of the attraction of the Mediterranean fruit fly, *Ceratitis capitata*, to kerosine oil by Devonish[1] in 1907, petroleum oils have been the object of extensive researches as a control measure against this insect (Compere[2], Ehrhorn[3] and Severin and Severin[4]) Petroleum oils are known to attract insects belonging to very different groups , for example, coccinellids, parasitic Hymenoptera, ants, winged aphides, gnats and moths (Severin and Severin[5]) Imms and Husain[6] exposed kerosine oil on four occasions and, in one exposure, they recorded the attraction of a number of Nematocera Morgan and Crumb[7] mention the attraction of a few bees and a considerable number of large flies, principally Sarcophagidinæ, to petroleum derivatives including crude petroleum, paraffin oil and kerosine.

During an attempt to study the chemotropic responses of insects to various odorous substances at the Punjab Agricultural College, Lyallpur, India, under the guidance of Prof M. Afzal Husain, it was discovered that *Forcipomyia* sp. (Diptera, Chironomidæ) was attracted to petroleum oils in specially large numbers

In these experiments, the Minnesota fly trap (Washburn[8]) was employed The traps were hung up in fields every afternoon and brought back to the laboratory next morning, where they were fumigated with hydrocyanic acid gas and the entrapped flies counted A trap containing crude petroleum oil captured a mean weekly total of 402 examples of *Forcipomyia* from October 24 to December 31, 1924; the maximum being 1078 flies in one week, and 275 flies in a single night on November 2, 1924 During winter, the number of flies decreased rapidly and from January to March 1925, a mean weekly capture of only 9 flies was obtained. The following different *grades of petroleum oils* available in the market were also tried petrol ; kerosine oil ; crude oil used for combustion in crude oil engines ; residual oil left after the preparation of coal gas.

It was noticed that petrol which contains hydrocarbons with low boiling points was the least attractive With the view of confirming this observation a sample of kerosine oil was distilled, and fractions distilling below 80° C , at 80°–158°, 158°–184°, 184°–220°, 220°–250° and above 250° C. were separately collected and exposed as usual It was discovered that fractions distilling between 158° and 184° C attracted the largest number of flies, while those distilling below 158° C. proved to be least attractive

In almost all cases of chemotropic responses of insects, males have been attracted in much larger numbers than the females, which reduces the value of these methods as a control measure [Compare *Dacus zonatus* to citronella oil, 3 females to 1,000 males (Howlett[8]), *Ceratitis capitata* to kerosine oil, 3 females to 1,000 males (Severin and Severin[4]), *Swammerdamella* sp to cinnamic alcohol, one female to 40 males (Morgan and Crumb[9])] In the case of this chironomid, however, it is interesting to note that the females were attracted in a very great majority and constituted 91 2 per cent of all the individuals captured

Nicotine Spray for the Apple Sawfly

IN some preliminary experiments carried out here in 1933 by G L Hey and myself, it was found that the egg of the apple sawfly, *Hoplocampa testudinea*, Klug, can be killed by means of a spray containing 0 05 per cent nicotine and 0 5 per cent commercial soft soap

It has for some time been thought that the egg of this insect is susceptible to such a spray only shortly before eclosion, that is, after the rupture of the chorion Our experiments, however, show that the egg is vulnerable right from the time it is laid

The detailed results of these experiments, and a discussion of their practical implications, will appear in the next issue of this Station's "Annual Report"

Mechanism of Detonation in Lead Azide Crystals

GARNER and Gomm[1] and also Muraour[2] have distinguished between the energies of activation (critical increments) which characterise (*a*) the thermal decomposition and (*b*) the detonation of an explosive In the case of lead azide, the value[1] for the detonation, 150,000 cal/mol (one extreme measurement, 9 7 sec, is omitted advisedly and with Prof. Garner's concurrence), is about *three* times that for the thermal decomposition, 47,000 cal/mol

The crystalline structure has also been examined As determined by Miles[3], the unit cell contains twelve molecules of PbN_6 In this department, however, the radiological directorate[4] has examined lead azide in more detail, the *c*-axis of Miles is doubled, giving the cell twenty-four molecules, and the space group is found to be Q_h^{18}. It follows from this that these twenty-four molecules are arranged in eight groups each containing *three* molecules of PbN_6

The recurrence of the value three is evidence that the criterion for detonation is closely related to the crystalline structure, and would indicate that the thermal decomposition is caused by the activation of a single molecule of PbN_6, whereas the detonation requires the simultaneous activation of all three constituents of one of the complex groupings $(PbN_6)_3$

Vapour Pressure of Potassium Amalgams

IF a solution of a substance has a smaller surface tension than the pure solvent, the solute is adsorbed or concentrated at the surface, in accordance with Gibbs's theorem It is therefore to be expected that the vapour pressure of the solvent of such a solution will be higher, when the concentration of the solute is made the same in the surface as in the interior, by continually renewing the surface, than when it is not

The following facts, found by measuring the vapour pressure of mercury over potassium amalgams, by determining the absorption of the resonance line 2537 A at room temperature seem to confirm this conclusion

Diluted potassium amalgams show a much greater lowering of the vapour pressure of the mercury than would correspond with Raoult's law (an amalgam containing 1 5 atom per cent of potassium showed 30 per cent lowering of the vapour pressure) If, by careful motion, the surface is continually renewed, the vapour pressure rises almost to the value predicted by Raoult's law Soon after the motion is stopped, the vapour pressure returns to the former low value

The same phenomenon is caused by impurities in mercury which is not especially cleaned

The above results explain Pohl and Pringsheim's observations[1] on the very small dependence of the sensibility and threshold of the photo effect of potassium amalgams on the concentration

Influence of Pressure on the Spontaneous Inflammation of Hydrocarbons

MESSRS NEUMANN AND ESTROVICH have recorded[1] some experiments on the conditions of spontaneous inflammation of the mixture $C_5H_{12} + 8\,O_2$ when heated in an iron bomb and in a bomb the inner surface of which was covered with gold The peculiar relation which they find between pressure and ignition-temperature also appears in some unpublished work of the late H B. Dixon.

In his experiments Dixon determined, at pressures ranging from 10 to 120 cm., the lag on ignition of a jet of pentane vapour heated to a predetermined temperature and issuing into an atmosphere at the same temperature. The shorter the lag, the less is the experiment liable to complications from surface effects. It is, therefore, significant that Dixon's results, as shown by the full-line curves in the accompanying illustration (Fig 1), are of the same general character as those of Neumann and Estrovich, as shown by the broken curves.

The Velocity of Light

IN 1927 there was published in these columns[1] a table of all the determinations of the velocity of light which I compiled from the original memoirs, together with a discussion, and I pointed out that except a pair of practically simultaneous values obtained in 1882 the final values (printed in heavy type) indicate a secular decrease of velocity. The last (and lowest) value given is 299,796 ± 4 km /sec. for 1926.

Since then, two determinations have been made: the first by Karolus and Mittelstaedt (1928) using a Kerr cell, to the terminals of which an alternating potential was applied, for interrupting periodically the luminous beam, instead of a toothed wheel[2]. A frequency can be obtained in this way, of the order of a million per second, which can be accurately calculated, thus permitting a very short base to be used (41 386 metre) without any loss of accuracy. The value found (mean of 755 measurements) was 299,778 ± 20 km /sec The second recent determination is mentioned in NATURE of February 3, p. 169: it gives for the velocity of light in 1933 the value 299,774 ± 1 or 2 km /sec

The determinations of this so-called constant made during the last ten years (the most accurate of the whole series) are therefore ·

1924 .	299,802 ± 30 km./sec.
1926 ..	299,796 ± 4 km /sec.
1928	299,778 ± 20 km./sec
1933 . .	299,774 ± 1 or 2 km /sec.

No physicist, looking at the above table, can but admit that the alleged constancy of the velocity of light is absolutely unsupported by observations. As a matter of fact, the above data, treated by Cauchy's method[3], give the linear law.

$$V_{\text{km./sec}} = 299{,}900 - 4T_{(1900)\ \text{years}}$$

When I first pointed out this fact (in 1924) it was objected that the data available were inconclusive, because the probable errors of the observations were greater than the alleged rate of change Sir Arthur Eddington has dealt the death blow to the theory of errors[4] and "this theory is the last surviving stronghold of those who would reject plain fact and common sense in favour of remote deductions from unverifiable guesses, having no merit other than mathematical tractability"[5] Even "die-hards", however, may fruitfully meditate over the 2nd and the 4th values in the above table

Graphical Determination of Contemporaries

I REGRET that Mr Dufton[1] is unable to find in my letter[2] on the above subject any clue as to what I am "trying to do", others from whom I have heard seem to have had no such difficulty.

The reproduction of Thomas Young's diagram[3] is interesting, but a diagram given by Prof Raymond Pearl in a paper[4] which he has kindly sent me gives all the information much more clearly and in such a form as to make it of real use to writers and teachers

There is no ground for the implication made by means of the quotation introduced apparently with this object only, since it is impossible by search to find matter which is quite unrelated to the title of the work in which it is included.

Research Items

Earliest known Miracle Play Mr T H Gaster describes in *Folk Lore*, vol. 44, pt 4, what he believes to be the text of a mumming play or representation in action of a ritual poem from cuneiform tablets found at Ras Shamra The text, written in a very obscure proto-Semitic dialect, describes a combat between two gods, which it is suggested was recited by priests while a religious pantomime represented the action As the tablets date from the middle of the second millennium B C, if this interpretation is correct, this would certainly be the oldest extant text of a miracle play The text describes what is apparently a ritual combat between summer and winter which is familiar in primitive and popular seasonal ritual from many parts of the world One of the gods is Aleyan-Baal, god of rains and verdure, and the other Mot or Death, god of aridity and blight The poem opens at the point where Mot has ousted Aleyan Baal from his dominion A new king is chosen and his accession to the throne is described Through the intervention of Anat, the virgin war goddess, Mot is routed, his royal garments torn from him, he is stabbed and gashed, cast into streams, fished out and finally given dominion over the underworld Aleyan-Baal is restored, the earth revives, sanctuaries are built in his honour, fires are lit for six days, and sacrifices offered In Syria, Mot, although corresponding to winter elsewhere, would be the period of drought in the summer, when all vegetation dies, and the return of Aleyan Baal would take place with the coming of rains in the autumn It is probable, therefore, that the festival at which the pantomime was performed took place at the 'New Year' in September The details of the poem correspond with the pattern of the ritual adopted throughout the world in ceremonies of 'Expelling the Death'

The Alizarin-KOH Method of Staining Vertebrate Skeletons An abstract of a preliminary note on this subject, by Mr M Rahimullah and Prof B K Das, appeared in Nature of February 4, 1933, p 171 The authors now send their published account (*J Osmania Univ Coll*, Hyderabad, Deccan, 1, 1–3, 1933), illustrated by photographs of successful preparations There is nothing of importance in this paper that is new, for the method is fairly generally used in Great Britain and in the United States, and adequate accounts are published in Gatenby's edition (1928) of Bolles Lee's "Microtomists Vade-mecum", and in the *Museums Journal*, 28, No 11, 1929 The *Museums Journal* article, by Peter Gray, states that the alizarin-KOH method is not suitable for small fish It has, however, been used with success for very small fishes by Parr and by Gloria Hollister in the United States, and by the writer of this note in Great Britain, the process often being complete in a few days Gray records alternative alcohol-alizarin methods, which are probably more suitable for permanent preparations of larval fishes. He acknowledges his indebtedness to Mr. H W Parker of the British Museum (Natural History), who was probably the first to perfect the alizarin-KOH method in Great Britain To the former abstract of the note of Rahimullah and Das it may now be added that, if the soft parts are to be dissected away from the stained skeleton, care must be taken to avoid excessive maceration in the KOH solutions A skeleton so prepared must be kept in a sealed jar of fluid (glycerin or xylol is suggested) and is not suitable for handling The authors emphasise the necessity for prolonged hardening in alcohol before using the KOH solutions

Burmese Earthworms In a paper recently received, Mr G E Gates continues his researches on Burmese earthworms, reporting on a large collection which has been carefully gathered from many little-known regions ("The Earthworms of Burma" III The Megascolecinæ *Rec Indian Mus*, **34**, Part 4 Dec 1932) 192 pages are taken up with this sub-family alone and there are more than fifty species of the genus *Pheretima* Interesting facts are shown in *Pheretima alexandri*, which is usually heavily parasitised by both nematodes and gregarines or by large numbers of spherical or ovoid cysts in the anterior portion of the body, especially in the seminal vesicles, the dorsal surface of the pharynx and the dorsal blood vessel, and part of the intestine It is found that abnormalities occur in these parasitised worms in connexion with secondary sexual characters as distinct from the gonads, the worms being quite normal externally and of the usual size The author states that the development must have progressed normally up to or nearly up to the time when the secondary organs began to develop, the cause of the abnormalities not being embryological but something that must be looked for in much later stages The subject is an interesting and important one and would probably lead to valuable results if studied in detail It is unfortunate that most tropical earthworms can only be obtained in certain seasons; for a considerable portion of the year they cannot be found, the period of drought extending in Burma from November well into June

Ghost Moths of Australia The Hepialidæ or ghost moths comprise some of the most archaic of all moths and occur in greater abundance in the isolated continent of Australia than in any other region of the globe They include some of the most gigantic and also some of the handsomest of known moths, while as caterpillars they are mostly subterranean in habit or form galleries in trees In order to obtain a true conception of the family, therefore, the Australian forms are of prime importance Mr Norman B Tindale, of the South Australian Museum, has undertaken their revision and the results of his studies are in course of publication in the *Records of the South Australian Museum* Up to date, Parts 1 and 2 have been issued during 1932 and 1933 these are well illustrated and are accompanied by careful diagrams of the venational and other characters of each genus

Root and Crown Rot of Peonies. An article on "Control of Crown and Root Rot of Peonies in America" on p 114 of the *Gardeners' Chronicle* of February 17 summarises a paper by Nellie A Brown in the American Peony Society's Bulletin Hot water treatment of peony roots has been used to combat eelworm, but will also control crown and root rot and Lemoine disease. Roots are submerged in water at a temperature of 120° F. for half an hour, but it is advisable to cut out rotten portions so far as practicable Very severely diseased plants may require treatment in two successive years, but this would disturb the plants more than most gardeners would desire.

The Limits of the Antarctic. The limits of antarctic regions have frequently been discussed. One boundary that has found some acceptance is that of floating ice, which with certain deviations makes the parallel of lat. 60° S. the approximate line. Supan suggested the mean isotherm of 10° C. of the warmest month, but inasmuch as that includes the forests of Fuegia within antarctic regions it is clearly unsuitable. Nordenskjöld, laying greater stress on the mean temperature of the coldest month, found a boundary nearer to lat. 50° S. than 60° S. and excluding all Fuegia. The mapping of the antarctic convergence in the waters of the Southern Ocean by *Discovery II* may furnish the best boundary. This change in water conditions was noted in a recent lecture to the Royal Geographical Society by Mr. Dilwyn Jones. It is the junction of the cold heavy antarctic surface water and the warm but more saline sub-antarctic surface water. The *Discovery* found that it was easily detected in all longitudes by a sharp change in temperature accompanied by corresponding climatic changes, almost equivalent to passing from winter to spring. Biologically, the convergence separates the area of *Euphausia superba* to the south from *E. Valentini* and *E. longirostris* to the north. The line runs for the most part in the latitude of about 50° S. but dips to below 60° S. in the longitude of Cape Horn.

Mexican Earthquake of January 14, 1931. Prof. J. Lacoste has made a careful study of the records of this earthquake (Pub. Bureau Cent. Séis. Intern., Monographs, fasc. No. 5, 3–58, 1933), and has prefaced it with a valuable list of 276 Mexican earthquakes during the years 1905–30. The majority of these earthquakes originated in three submarine zones, the centre of the first being in lat. 12·5° N., long. 90° W., of the second and more important in lat. 16° N., long. 97° W., and of the third in lat. 34° N., long. 118° W., all three lying along a band passing through the Acapulco Deep. The earthquake of January 14, 1931, occurred at about 6.55 p.m. and was recorded at all stations throughout the world. The shock, which lasted four minutes, destroyed completely the city of Oaxaca. Prof. Lacoste places the epicentre in lat. 15° 30′ N., long. 96° 25′ W., belonging therefore to the second of the above zones, and lying to the east of the Acapulco Deep, near the isthmus of Tehuantepec. To determine the depth of the focus, he uses Berlage's method based on the interval that elapses between the arrival of the first wave and that of the same wave reflected at the surface. The average of seven estimates is about 45 km. or 27 miles.

New Method of Photographic Photometry. In ordinary photographic photometry, the blackening of the plate is determined by passing a beam of light through the plate and measuring the absorption. A number of microphotometers have been devised for doing this. Brentano, Baxter and Cotton have recently described measurements of the light scattered by the silver particles in the photographic image (*Phil. Mag.* (Supplementary Number), February). In the experiments described, the test plates were made by exposure to X-rays, and for small densities the proportionality between X-ray exposure and scattered light was very close. Much smaller densities may be examined by this method than by absorption microphotometry, and it is therefore interesting to find that no threshold value was found for X-ray exposure before proportionality set in. The method seems very suitable for the photometry of X-ray reflections obtained in the rotation, powder, and Laue examination of crystals, for the proportionality between scattering and exposure enables the photometer to make an automatic integration of the effect over an appreciable area. It seems best to have a fine-grain emulsion and a filtered red light in the scattering photometer, using the light scattered in the range 6°–15°. Scattering from the surface of the emulsion and particularly from scratches is a serious complication, and it was found an advantage to cement a cover glass over the emulsion to reduce this scattering. The authors say that the accuracy obtained may be as good as 0·2 per cent of the limiting blackening for which proportionality can be obtained.

Attempt to Detect a Neutral Particle of Small Mass. Chadwick and Lea have recently published the negative result of an experiment designed to examine the possibility that the continuous β-ray spectrum is accompanied by the emission of penetrating neutral particles (*Proc. Camb. Phil. Soc.*, 30, Part 1). The energies of those particles might be distributed in such a way that they combine with those of the β-particles to form a constant energy of disintegration, a low energy β-particle being associated with a high energy 'neutrino'. A strong source of radium D + E + F (radium E gives a well-marked continuous β-ray spectrum) was placed near a high-pressure ionisation chamber and an absorption curve was taken with lead screens. The radiation was all identified with the radium E and polonium γ rays. If neutral particles are emitted, it is calculated that they cannot produce more than 1 ion pair in 150 kilometres path in air. A consideration of the possible nature of the particle shows that, if it exists, it must have small mass and zero magnetic moment.

Movement of Flame in Firedamp Explosions. The Safety in Mines Research Board has recently published Paper No. 82 entitled "The Movement of Flame in Firedamp Explosions" by H. F. Coward and R. V. Wheeler. The paper begins with the simplest type of firedamp explosions and goes on to more complicated cases. The scheme of the paper is that of giving the theory first and then of illustrating it by the results of various experiments. The introduction reminds us that "the lower and upper limits of inflammability of firedamp in air are roughly 5 and 14 per cent of firedamp, and that in a 9·5 per cent mixture, the so-called 'theoretical mixture', the firedamp and oxygen are in the proportions required for their complete combustion on explosion". After considering the general theory the paper goes on to discuss the propagation of flame in plain tubes, first as a uniform motion, secondly as a vibratory motion, and then describes the effects of narrow tubes, perforated plates and other types of constriction. The authors point out that the speed of propagation of a firedamp explosion may vary from zero to approximately 2,000 yd. per second, and the paper concludes with a warning that although a thorough knowledge of the theory of the subject is most helpful in interpreting any colliery explosion, the underground conditions, which in a colliery are usually exceedingly complex, must be thoroughly studied before attempting to apply the theoretical considerations set forth in this pamphlet.

Insect Pests in England and Wales*

A RECENT official report on crop pests in England and Wales covers the years 1928–31 and forms *Bulletin* 66 (1933) of the Ministry of Agriculture and Fisheries In this publication, Mr. J. C F Fryer, director of the Ministry's Plant Pathology Laboratory at Harpenden, reviews the general position over the period mentioned.

In methods of pest control, definite progress is evident with regard to enemies of fruit and other horticultural crops The English grower to-day, provided he can achieve the desired result, adopts insecticidal measures on a scale as thorough as those employed in the Dominions and the United States The progressive man realises that, to produce good sound marketable fruit, spraying is not merely an advantage, but is also an absolutely essential part of cultural routine.

In the use of dry sprays or dusts Great Britain is, however, a long way behind. It is nevertheless becoming recognised that they have definite advantages in point of ease and speed of application and reduced costs Their adoption does not seem likely to come into practice until certain initial difficulties have been overcome. Many of the improvements in control measures have resulted from investigations carried out by members of the Research and Advisory Services of the Ministry of Agriculture. New winter spray fluids have emanated from the Long Ashton Research Station

Much work has been done in connexion with pyrethrum. It has been shown that this plant can be grown satisfactorily in many parts of England. The problem as to whether the growing of the crops is an economic proposition is now being tried out. At Rothamsted, progress has been made in methods of evaluating the toxic principles found in the pyrethrum flowers. Also, experiments have been conducted with pyrethrum sprays in connexion with horticulture, which show promise, and there is little doubt that considerable developments in this direction are probable.

The entry of foreign pests through the agency of commerce, or other means, forms the second part of this *Bulletin* During the period under review the apple fruit fly (*Rhagoletis pomonella*) was detected in consignments of low grade apples from the United States Since it is a serious pest, likely to thrive under English conditions, the Ministry issued the Importation of Apples Order 1930 entirely prohibiting the entry of certain grades of apples from the United States within a specified period each year. Among other immigrant pests the cherry fruit fly, chrysanthemum midge and cottony cushion scale are briefly noticed Reference is also made to an introduced insect of a beneficial character, namely, the chalcid wasp *Aphelinus mali* This insect has proved itself at times to be capable of controlling the woolly aphis under English conditions Whether it is capable of persisting from year to year is very uncertain, and it appears to have failed in many cases owing to unfavourable climatic conditions It is therefore still doubtful whether this useful parasite can be permanently acclimatised or whether it will need to be reintroduced every few years from colonies grown under protected conditions.

The major part of the *Bulletin* is devoted to a review of the prevalence of each specific crop pest during the four years under consideration The attacks of cereal and grassland insects, for example, were, on the whole, below the average Vegetable enemies, especially root flies, caused a good deal of destruction in various parts of the country but the most serious pests were those affecting orchards Especially injurious were the apple capsid and the apple sawfly. Among strawberry pests the 'red spider' (*Tetranychus telarius*) was very destructive in 1929, when it appeared for the first time in epidemic form. in subsequent years it showed a marked decline Mention needs also to be made of the great prevalence of the aphis, *Myzus cerasi*, on cherries in Kent which was a feature in 1928 severe infestations also occurred in the south-west of England during 1931

The *Bulletin* concludes with a useful list of papers published during 1928–31 in various journals and bearing upon subjects dealt with in its pages

Petrogenesis of the Newry Igneous Complex

IN her paper on "The Eastern End of the Newry Igneous Complex", which was read before the Geological Society on February 7, Miss Doris L. Reynolds made a contribution to petrogenesis of outstanding importance. The rocks described are types common to many orogenic regions, and include peridotite, biotite-pyroxenite, augite- and hypersthene-monzonite, augite-biotite-diorite and granodiorite These are convincingly shown to be derivatives, not from basaltic or granitic magmas (gabbro and granite being absent from the area), but from three primary sources, two of which have hitherto remained unsuspected. The three parental materials now recognised are (*a*) ultrabasic magmas rich in potash; (*b*) Silurian sediments which became fused by contact with the latter; (*c*) a magma represented almost entirely by plagioclase. The conclusions reached are supported by a suite of detailed analyses made by Mr. L. Theobald and Prof. H F Harwood

The earliest intrusions were peridotite and biotite-pyroxenite, the latter representing a residual magma produced by the abstraction of early-formed olivine and pyroxene from peridotite magma The ultrabasic magmas rose into graywackes and shales and became surrounded by a zone of selective fusion now represented by a fine-grained massive rock that is seen in all stages of development.

The ultrabasic magmas, which were too dense to rise by stoping, came into place partly by shouldering aside the enclosing sediments, as shown by the way in which the strike lines deviate from the regional Caledonian trend and curve round the contacts, and partly by soaking into the overlying zone of fusion, thus giving rise to augite-monzonite.

Simultaneously with, and also subsequent to, the intrusion of the ultrabasic rocks, a plagioclase magma invaded and hybridised them with the production of augite-biotite-diorite. The latter rose in turn into the zone of fusion, giving rise to hypersthene-bearing monzonites and diorites.

The granodiorite appears to have risen by stoping, since it is rich in xenoliths of the earlier hybrids and cuts across the sediments in the north-east. In places it transgresses the zone of fusion and contains xenoliths of the fused sediments. Textures and mineral and chemical composition unite in suggesting that the granodiorite is essentially a mixture of sediments and plagioclase magma with a little biotite-pyroxenite. For the most part, it clearly formed in depth and afterwards rose into its present position. The porphyritic granodiorite of Cam Lough Mountain in the west of the Complex represents the simple soaking of plagioclase magma into fused sediments.

An animated discussion followed the reading of the paper. A number of speakers, including Dr. W. Q. Kennedy, Dr. H. H. Thomas, and Mr. W. Campbell Smith, seemed suspicious about the existence of a plagioclase magma, and it was asked whether a granite magma might not be competent to produce the observed results. Miss Reynolds pointed out that since the augite-biotite diorite is a normatively undersaturated rock almost free from quartz, it is impossible that the addition of granite to the biotite-pyroxenite could have produced it. That the plagioclase came in as a magma is indicated by the observation that it has dissolved all the iron ores with which it has come into contact in the biotite-pyroxenite. From the analyses it was found that the magma is composed of about 80 per cent plagioclase, with iron ores and biotite making up the balance.

Prof. A. Holmes suggested that elsewhere there is ample evidence of plagioclase magma in the existence of anorthosites. Such magma is likely to be very hot, and by syntexis with crustal rocks it would readily grade into syenitic magma, thus providing a wide range of felspathic magmas. Questions of origin are purely speculative, but this does not mean that the plagioclase magma traced by Miss Reynolds is in any way hypothetical; its behaviour and products are demonstrable facts of observation. He welcomed the new light that the evidence from Newry will throw on the less tractable problems of volcanic fields such as that of Bufumbira. The lavas of that region include potash-rich limburgites in which he had recognised the volcanic equivalent of biotite-pyroxenite. Leucite basanites developed by the incoming of plagioclase, and by the further addition of sialic material latites and hypersthene-trachyandesites were generated.

Prof. A. Brammall pointed out that while the well-known Hollybush diorite of the Malverns might theoretically be referred to the granitisation of greenstones, neither field nor geochemical evidence sustains this view; all the evidence points to a genetic linkage with the biotite-pyroxenite that is present in the area. The formation of the diorite requires the addition to the biotite-pyroxenite of a magma composed of 60 per cent of andesine and rich in iron ores.

As illustrations of other igneous assemblages where there are signs of an ancestry comparable with that of the Newry Complex, Miss Reynolds cited the Loch Ailsh Complex of Scotland, the provinces of Monzoni and Predazzo, the Trondhjemite-Opdalite Series of Norway, the Cortlandt Series of the Appalachians and various examples in the Western Cordillera of North America, including the Rossland Complex described by Daly. She directed attention to the noteworthy fact, hitherto obscured by faulty nomenclature, that true gabbros are characteristically absent from many of the plutonic complexes of folded regions. Referring to the occurrence of monzonites and diorites as individual intrusions, Miss Reynolds suggested that hybridisation, which is known to have taken place at shallow depths, implies more intense activity at greater depths, resulting in the production of actual magmas capable of intrusion to higher levels.

Magnetic Recording and Reproducing in Broadcasting

AT the Paris Universal Exhibition of 1900, Poulsen demonstrated his telegraphone as a magnetic speech recorder for use in a telephone circuit. The apparatus, in its earliest form, consisted of a steel wire or ribbon, which was passed between the poles of an electromagnet, the windings of which were supplied with the audio frequency currents to be recorded. As the wire was drawn slowly through the field of the magnet, it received therefrom a series of transverse magnetisations corresponding to the sounds received. On the completion of the record, the process could be reversed, and by passing the steel wire between the poles of another magnet connected in series with a telephone receiver, the speech was reproduced.

Various improved forms of the apparatus were developed during the next few years, and among these was one due to Pedersen, who in 1902 succeeded in recording two telephone messages simultaneously on one steel wire, and afterwards reproducing them separately in two receivers. In general, however, the telegraphone, like many other inventions, found little application in connexion with communication technique, until it was given a new lease of life by the introduction of broadcasting.

It is now several years since the Blattnerphone, a modern form of this magnetic recorder, was introduced for recording speech and sections of programmes required for broadcasting purposes. It soon became apparent that the magnetic recording system had important advantages over the use of films or wax discs for this purpose. Among these advantages are the freedom from chemical processes, and from delicate mechanical adjustments, and also the facility with which the recording strip can be 'cleaned up' for repeated use.

The latest form of this apparatus for commercial use in Great Britain, known as the Marconi-Stille equipment, formed the subject of an article in the *Wireless World* of January 5, and was also demonstrated by Marconi's Wireless Telegraph Company, Ltd. at the recent Physical Society's exhibition. The Marconi-Stille machine provides an uninterrupted record of thirty-five minutes duration, and it incorporates the necessary mechanism for driving the steel tape at a uniform speed through the electromagnetic apparatus, which produces a varying magnetic flux in the tape in the case of recording, or translates the magnetic record into currents of varying amplitude for reproduction purposes. The steel tape is driven by synchronous motors at a normal speed of 90 metres per minute, between two drums similar to those used in a cinematograph film projector In its passage the tape passes in succession through three pairs of special bi-polar electromagnets, which are used in turn for 'wiping-out' any previous record, for recording and for reproducing The heads carrying the two latter sets of magnets are provided with micrometer adjustments for controlling the separation of the pole pieces, since this adjustment affects the response characteristics The three heads of the apparatus are connected by screened twin leads to their appropriate places on the amplifying and control panels, and means are provided for obtaining the correct level required for recording and reproduction. The recording magnet is also supplied with auxiliary direct current to operate the tape at the best part of the magnetisation characteristic for recording A suitable audio-frequency correcting circuit is connected in the reproducing amplifier, and the proximity of the recording and reproducing heads on the apparatus enables an instantaneous comparison to be made between the input signals and the output from the equipment

The magnetic record, once made, is permanent and may be utilised any number of times until it is wiped out by the demagnetising process for use on another programme. The whole process now finds widespread application in broadcasting services, particularly for the relaying of important or interesting programmes at different times

University and Educational Intelligence

CAMBRIDGE —J. Yudkin, of Christ's College, has been appointed to the Benn W Levy research studentship in biochemistry

Smith's prizes have been awarded to the following candidates : K Mitchell, of Peterhouse, and A J Ward, of Emmanuel College

Rayleigh prizes have been awarded to M S Bartlett, of Queen's College, and C G Pendse, of Downing College.

Grants from the Worts Fund have been made as follows :—£50 to N Bachtin towards the expense of a journey to North Thessaly, £50 to I. H. Cox towards his expenses as geologist in the Parry Islands, £50 to J J Keigwin towards the expenses of an expedition to the Zambezi Valley, £50 to P W. Richards towards the expense of a botanical expedition to South Nigeria, £40 to W Graham-Smith for palæontological investigations in Canada, £25 to C. W Borgmann for metallurgical research in Sweden, £25 to J W. S. Pringle towards the expenses of the Cambridge Freshwater Biological Expedition to South Morocco, £10 to J W. Welch for expenses in connexion with his study of the Qaoko tribe.

The managers of the Balfour Fund have made a grant of £50 to C Forster-Cooper, of Trinity Hall, for researches on the fauna of the Achenarass Quarries.

J. H. Lochhead, of Christ's College, has been nominated to use the University's table at the Zoological Station at Naples from April 1 until September 30, 1934.

LEEDS —The Vice-Chancellor, on behalf of some two hundred subscribers, presented on March 9 to Prof. Walter Garstang a radiogramophone and a cheque, as a token of appreciation from colleagues, pupils and other friends at Plymouth, Oxford, Lowestoft and Leeds Prof Garstang retired from the chair of zoology last year

LONDON —The following degrees have recently been awarded . D Sc (Econ) to A E Feavearyear (private study) for two published works entitled "The Pound Sterling A History of English Money", and "Spending the National Income" and D Sc in physics to W. E Williams (recognised teacher at King's College) for ten works on interferometry.

SHEFFIELD —The following appointments have been made Dr E J Wayne, to the chair of pharmacology , Dr James Clark, to the lectureship in infectious diseases , Mr H Laithwaite, as junior research assistant in the Department of Glass Technology

THE Board of Education is prepared to consider applications for full-time studentships from teachers with at least five years' teaching experience who desire financial assistance to follow courses of advanced study at universities or other institutions at home or abroad Particulars of the awards and application forms are obtainable from the Board of Education, Whitehall, S W 1

Science News a Century Ago

Capt. John Ross Honoured

In 1829, thanks to the generosity of Sheriff Felix Booth, Capt John Ross had been able to fit out the steam vessel *Victory* for arctic exploration Ross sailed in May 1829 and returned home in October 1833 in the *Isabella*, the *Victory* having had to be abandoned in the ice On March 27, 1834, at a Court of Common Council, Ross was presented with the freedom of the City of London. In making the presentation, Sir James Shaw, the Chamberlain of the City, said "Captain Ross—The City of London have ever been forward in bestowing the honour of their freedom on eminent men who have distinguished themselves in the service of the public In your person science has been largely and specially indebted for the zeal, public spirit and disinterestedness shown by you in fitting out and taking charge of an expedition, with the patriotic view to the solution of the problem whether a north-west passage existed to the Pacific. For the courage and perseverance which have marked the whole of your proceedings in this hazardous enterprise, and for the admirable skill and address manifested by you, with the blessing of Heaven, in preserving life and health and harmony amongst your brave companions, amidst the privations and hardships of four years' navigation in the Arctic regions ,—for these services the Corporation of London have recorded their grateful thanks by presenting you with the freedom of their ancient city in a box of British oak."

J. D. Forbes at Edinburgh

When J. D. Forbes in 1833 was appointed to succeed Sir John Leslie as professor of natural philosophy in the University of Edinburgh, he was not twenty-four years of age and had held no appointment before When preparing his lectures, he wrote to Whewell for advice on various points, especially in regard to textbooks, for he felt that the textbooks used at Cambridge would be useless for his class at Edinburgh, owing to the then low state of mathematical knowledge among Scottish students. He consulted Whewell on many points in natural philosophy and mechanics, and towards the close of his first session, on March 29, 1834, wrote to Whewell: "I find the greatest advantage from having been obliged to study these subjects in a way necessary to convey a precise idea of them to others, which I feel that almost no other circumstance would have induced me to spend so much labour upon. . . A month hence, I shall have finished my course, and then propose to escape for a little relaxation. I shall probably go to London, and hope to see you. I am certainly relieved at having got well through so much of my course. The responsibility I felt was oppressive. But my labours have been more than rewarded by the efforts of my pupils, and the obvious improvement in the method and degree of study which has been the consequence. I have given about twenty lectures to the more advanced, going as far as 'Poisson's Demonstration of the Direct Problem of Central Forces', which, humble as it may appear to you, is a step among us 'hyperborean sages'."

Steam Road Carriages

In the first third of last century, steam road carriages were made by many inventors, including Trevithick, Gurney, Hancock, Church, James, Squire, Maceroni and Dance, and some of the vehicles were used for regular passenger services. Two other pioneers were Richard Roberts and John Scott Russell. A carriage made by Roberts made an experimental trip in December 1833, followed by a second three months later. On March 29, 1834, the *Manchester Advertiser* said, "on Thursday the carriage started from the works in Falkner-street at half-past six in the evening under the guidance of Mr. Roberts, with upwards of forty passengers. It proceeded about a mile and a half up Oxford-road, namely, to near the end of Nelson-street, where owing to an apprehension of a deficiency of water, a sudden turn was made. The breadth of the road at this point was insufficient to allow of free scope for the engine, and about six minutes were occupied in making the turn. The carriage then proceeded back to the works where it arrived without accident just nineteen minutes after starting. The maximum speed on a level was twenty miles per hour." On April 4 the carriage was taken out again, but the trial was stopped through the failure of the boiler tubes.

Of Russell's carriage the *Weekly Dispatch* of March 30 said: "A new steam-carriage [Mr. Russell's] commenced plying between Glasgow and Paisley on Wednesday. The carriage is attended by a supplementary vehicle containing the necessary supply of charcoal and water. The carriage is superbly fitted up, holds six inside and twenty outside passengers, and is hung upon springs, quite free of the boiler and machinery. The boiler is extremely small and occupies the space immediately below the carriage while the boot contains the engines. The boiler is capable of generating steam in twenty minutes. The two engines fourteen horse power each situated above the hind axle are connected with it by cranks working at right angles to one another so as to produce continuous rotary motion."

Societies and Academies

London

Institute of Metals (Annual General Meeting), March 7. G. A. HANKINS and C. W. ALDOUS: Minimum dimensions of test samples for Brinell and diamond pyramid hardness tests. The metals investigated include copper, brass, aluminium and steel. A width of test-specimen of 4½ times the diameter of the impression is satisfactory for accurate Brinell tests. For Brinell tests, the limiting value of the ratio of thickness of test sample to depth of impression for accurate results appears to be a characteristic of the test material; a value of the ratio of 6 is required for mild steel, about 15 for copper and more than 20 for spring steel. For diamond pyramid hardness tests a limiting value of the ratio of test-sample thickness to impression diagonal of 1½ gives results which are practically independent of test-sample thickness except with soft copper and soft brass. I. G. SLATER: Note on the influence of gases in an 8 per cent copper-aluminium alloy on normal and inverse segregation. In a sand-cast ingot, 3 in. in diameter by 3 in., segregation is inverse with very gassy melts but normal with degassed melts. GILBERT RIGG: The diffusion of zinc and iron at temperatures below the melting point of zinc. When clean rolled zinc sheet is heated in close contact with clean iron, diffusion commences at below 300° C. and is fairly rapid at above 380° C.; it proceeds by the formation of cones of diffusion products, which spread out from isolated points where the contact between the metals is most perfect, and gradually penetrate into the zinc and across its surface. Two well-defined layers of diffusion products are formed, a thin layer of constant thickness (about 0·08 mm.) containing about 17 per cent iron being next to the iron, and a thicker layer containing 0–11 per cent iron outside this. On continued heating, the thin layer moves towards the zinc, being continuously converted into the zinc-rich layer; this would seem to indicate that the principal diffusion constituent is the iron. H. G. GOUGH, H. L. COX and D. G. SOPWITH: A study of the influence of the intercrystalline boundary on fatigue characteristics. With the object of studying the process of fatigue in relation to crystalline boundaries, tests under alternating torsional stresses have been made on three specimens of aluminium each consisting of two crystals. The distribution of slip bands showed that the effect of the boundaries on the distribution of stress was extremely slight, each crystal of each specimen behaving as if it alone composed the whole specimen. It appears that the presence of intercrystalline boundaries may considerably strengthen the constituent crystals against fatigue; but that the effect of the boundaries on the distribution or even on the amount of slip is very small. It is probable that the major effect of the boundary may lie in some restriction of strain that it imposes. C. E. PEARSON: The viscous properties of extruded eutectic alloys of lead-tin and bismuth-tin. Elongations up to 2,000 per cent have been obtained in tensile tests employing prolonged loading. An apparatus designed to maintain a constant stress on the test-piece during extension shows that deformation takes place at a uniform rate which is greatest in freshly extruded rods and decreases with age or on annealing. The viscosity is not that of simple liquids, but resembles that shown by some disperse systems in which the viscosity coefficient is a function of the stress causing flow. The locus of viscous flow is found to be at the intercrystalline boundaries. E. W. Fell : A note on some formulæ concerning viscous and plastic flow in soft metals In particular, the flow of the metal in a prolonged ball-hardness test is compared with the flow in tensile test-pieces under a constant stress per unit area of cross-section. A. Portevin and P Bastien : Castability of ternary alloys. The ability of a molten metal or alloy to fill a mould completely is termed 'castability'; it can be determined by ascertaining the length of a spiral cast-iron mould filled by the metal under predetermined casting conditions. The castability of a pure metal is a linear function of the difference between the pouring temperature θ and the melting point F; the slopes of the castability $(\theta - F)$ curves vary with the viscosity of the metal. The castability of binary alloys varies with the solidification range and with the mode of crystallisation, being greater when polyhedral crystals separate than when the primary crystals are dendritic. Maximum castability occurs with the eutectic composition and minimum at the limit of solid solubility The castability of ternary alloys generally varies inversely with the primary solidification range.

Prices of Scientific Books

THERE are few libraries of scientific books, whether they be those of universities or other institutions or of private individuals, which have not been compelled during the last few years to cut down their expenditure upon periodicals The loss is a loss to the library, to the scientific worker, and to the publisher, and has increased on the library shelves the much detested 'broken series'. Really the outcry on behalf of continuing old established series of periodicals may be more sentimental than rational ; it is impracticable and impossible for any institution to continue all the old series and add all the new, and there is no sufficient reason why an old periodical should be continued if it has degenerated in quality or if it can be replaced by one better suited to the needs of the users of the library Co-operation between libraries will often solve the problem of retaining the fullest possible range by avoiding duplication of the least necessary series

The question, however, arises and is pressing. Since libraries must cut down expenditure upon periodicals, could a cut be organised which will have some effect in nullifying the conditions against which the libraries are struggling ? We think it could

Amongst many other services, the American *Quarterly Review of Biology* performs the annual service of analysing the cost of biological books received for review by that journal The result of John R Miner's analysis is always illuminating, sometimes astounding, and has been referred to on more than one occasion in the pages of NATURE For 1933 the number of pages reviewed by the *Quarterly Review* was 104,725, and the comparisons are worked out on the average cost per page to the reader, the prices of foreign books having been converted into dollars at the rate current when the book was received

In the first place it is satisfactory to notice that the general trend of prices continues to be downwards , thus a decrease of 3·6 per cent from 1932 to 1933, and of 8·9 per cent from 1926 to 1933, has brought the average price of all the books reviewed to 1·005 cents a page This is in accord with the falling price of commodities in general throughout the world, but it is not so satisfactory to learn that the fall in price of biological books has lagged seriously behind the international decline "Thus the books published in the United States show a decrease in price of 8·9 per cent from 1926 to 1933, whereas the wholesale commodity price index of the United States Bureau of Labor Statistics declined about 40 per cent in the same period." The most striking decline in price has been in the books published in England (by which we imagine the author means Great Britain, for Scotland is by no means negligible as a producer of biological works), and there the fall from 0·89 to 0·66 cents a page represents more than 25 per cent. Since this difference, as converted into dollars, probably reflects the change in the relative value of the pound sterling, it is sad that we on this side of the Atlantic cannot appreciate it in buying our own books.

In the second place, it is noticeable that in spite of certain readjustments of price, a very marked discrepancy still exists between the prices of books published in different countries. Since the price comparison began in 1926, France has, until 1933, held pride of place for the cheapest commercially produced scientific books, but in 1933, with an addition to cost of 23·3 per cent, the price of 0·74 cents a page exceeds the cost of British books, which now are cheapest in the list.

We have not included in this comparison non-commercial books, such as Government publications the primary purpose of which is presumably propaganda for the good of the nation as a whole, for which end they are subsidised. Comparison of prices throws some light upon the value placed by governments upon the value of scientific work. U.S. Government publications are by far the cheapest in the whole list of publications, at 0·17 cents a page, for the encouragement of the application of scientific results, whereas the cost of British Government publications is 1·39 cents a page, *more than twice the price of commercial books*, and approaching very near to the cost of German books, which are the most expensive in the list. It would seem that either H.M. Stationery Office is inefficient as a producer of books, or that our Government does not consider the results of the work of its scientific staffs sufficiently valuable to be set before the public in the way deemed desirable in the United States. We suspect the presence of both adverse influences; but in any event it is difficult to understand why there should be this difference between the commercial price of British scientific books and the British Government price.

As to the discrepancy between the book prices of different countries: in 1933, while the French price rose 23 per cent, the German price fell 10 per cent, and yet in spite of that readjustment the price of German books is almost double that of French, 1·43 cents against 0·74 cents a page. The German prices for medical and scientific publications are so great in comparison with those of other countries (except British Government publications) that probably every scientific institution in the world has been discussing the matter as one of the serious library problems it has to face. There are several disturbing features. So great is the discrepancy that in most libraries of reasonable size a very large proportion of the annual grant for periodicals (two thirds or more in U.S.A. libraries) is swallowed up by expensive German publications chiefly in the hands of one or two large firms, leaving a third or less for periodicals from the rest of the world. That proportion clearly bears no relationship to the relative scientific value of the journals in question.

"The cost of some of these journals has now reached as high as 90·00 to 173·00 dollars a year, and as no definite yearly subscription price is announced, the subscriber cannot know beforehand what he will be called upon to pay." There is a remedy; it is a drastic one, but after mature consideration it has been adopted and recommended by the Medical Library Association, on the advice of a special committee which it appointed to inquire into the situation.

We quote in full the resolutions, as passed by the Association (*Science*, 78, 139; 1933), they may be helpful to the curators of libraries of scientific periodicals in Great Britain, suggesting that by co-operation an end may be put to what is no less than extortion, an exploiting of scientific workers, because of their desire to give due weight to the scientific results of every country.

"1. It is recommended that no library subscribe to any periodicals that do not have a fixed annual subscription price for the entire annual output of volumes or parts. That such price be stated in advance, and also a statement of the number and parts to be issued per year.

"2. That the Committee on the Cost of Current Medical Periodicals be empowered to invite the various library groups of this and other countries to co-operate with us in the above-mentioned and other measures, necessary to establish more equitable prices for medical and other scientific journals, and that the approach to library organizations in other countries be made first through the president of the International Federation of Library Associations.

"3. We believe there is a widespread opinion that there must be a substantial reduction in extent of, and in subscription prices for, the most expensive medical and other scientific periodicals,

> and we further recommend that, unless definite word to this effect is received prior to renewal of subscriptions for 1934, libraries cancel their subscriptions to the most expensive journals, except one library in each of 6 to 10 zones throughout the United States and Canada "

Some of our British universities have found the strain of German periodical subscriptions to be so great that they have already drastically cut down the list But isolated action penalises the pioneers and may not be sufficiently cumulative to have the effect desired , whereas co-operative action, even throughout the English-speaking world, could scarcely fail to bring about a more reasonable attitude on the part of the publishers concerned

J R

Protozoology in the United States

The Biology of the Protozoa By Prof Gary N Calkins Second edition, thoroughly revised Pp xii+607+2 plates (London Baillière, Tindall and Cox, 1933) 37*s* 6*d*

THE first edition of this book appeared in 1926, and was favourably reviewed in these pages at the time (NATURE, 118, 763, Nov 27, 1926) by another hand and since this new version is described as "thoroughly revised", one turns to it with confident hope that the shortcomings of the earlier volume have been, in the main, remedied According to the author's preface, the chief amendments are as follows

> "After the first introductory chapter we plunge at once in Chapter II into the substances and structures of the fundamental organization This is followed . by the development of those substances and structures into cytological derivatives (Chapter III) and taxonomic structures (Chapter IV) of the derived organization In Chapter V the general physiological activities are considered in anticipation of Chapter VI on reproduction. The problem of general vitality and its significance in fertilization and the accompanying phenomena of sex differentiation, maturation, reorganization, adaptation and variations are treated in Chapters VII, VIII and IX The special chapters on taxonomy, together with more elaborate keys to genera, are transferred from the middle of the book to the end in Chapters XI, XII, XIII and XIV."

This second edition also contains a new chapter entitled "General Ecology, Commensalism and Parasitism" As the author truly says, "Parasitism and disease should be considered in any work on general biology These topics were omitted in the first edition but are introduced here in Chapter X". In this chapter is included a discussion of the dysentery amœba of man (*Entamœba histolytica*), in the course of which the author insinuates that the present reviewer comes "rather close to unfair dealing" in his interpretations of history and nomenclature This charge should be answered at once, as it has already been singled out for commendation in the United States But it will suffice to note that Calkins's other allegations are here often clearly incorrect, and his conclusions demonstrably wrong For example, he tells us that Losch, in his classical case of amœbic dysentery, "found an abscess of the liver containing amebæ" . he gives Councilman and Lafleur credit for modern views which they did not express and he concludes, apparently, that the correct name of the parasite in question is "*Endamœba dysenteriæ* (*histolytica*)"—an unorthodox combination in which every term appears to be unjustifiable It may be noted further, as evidence of the author's own fairness and impartiality, that he finally assigns the reviewer s discovery of the complete life-cycle of the parasite *in vitro* to two later American imitators Calkins is obviously unfamiliar with this branch of his subject, and his excursion into it seems therefore regrettable

Unfortunately, many other pages in this book invite similar criticism The "thorough revision" which it has undergone has neither brought it reasonably up to date nor corrected scores of factual mistakes in the first edition and its precursors Proper names are still too often misspelled, or printed without their diacritical marks no magnifications are noted for most of the figures, so that composite pictures are likely to delude the uninstructed (for example, Fig 4, p. 23, where a *Chilomastix* cyst appears as large as an adult *Euglypha*) it is scarcely ever indicated whether the illustrations show living or fixed and stained specimens the fabulous figures of "mitosis in *Endamœba coli*" (Fig 26, p 53—rightly claimed as "original") are still unblushingly displayed · and the bibliography is still carelessly done and unrepresentative Many authors are hardly treated, and the references as a whole are still inadequate As an example, it may be noted that Wenyon, our leading protozoologist—whose name was omitted altogether from the "Bibliography" in the first edition—is now credited with only two publications, both bibliographically inexact. Most other living English protozoologists are ignored The "more elaborate keys to genera", so far as we have tested them in detail, seem more likely to mislead than to direct the beginner—for whom they are presumably intended

Some of the defects just noted are doubtless to be excused as survivals from earlier publications, yet even so it is hard to understand how they have escaped a reviser's eye. But Calkins is nothing if not conservative In 1901 he called the Father of Protozoology "Anton von Leeuwenhoek"—as though he were a German—and he called Ledermuller "Ledenmüller", and in 1933 he does so still. On the other hand, it should be added that both text and illustrations have now been slightly curtailed, while two coloured plates—borrowed from others—have been incorporated but there is also now only a single index (19 pages) instead of the separate author and subject indexes (25 pages in all) in the first edition, though the price has been increased by approximately 7 per cent

Errors in detail are present in every book ever printed, and we have no desire to lay undue emphasis on a few glaringly exhibited in the work under review A book may be good in general, though bad in particulars and the present volume must therefore be considered and judged also from a wider angle Yet this is very difficult, because—despite its rearrangements, additions, and corrections—no rational plan seems to underlie the work as a whole It seems still to be a medley of morphology, systematics, and physiology, precariously held together by loose generalities, while the very title, with its undefined term "biology", is apt to mislead us regarding the author's aim—if any But it is "unfair dealing", perhaps, to ask for greater precision, since he tells us in his opening lines that he "has made no effort to give a complete account of the Protozoa" but "rather a study in biology illustrated by the unicellular animals". This is certainly very vague, yet it may possibly be brought to a sharper focus by the fine-adjustment of history—a method of approach to his subject for which the author himself has evidently but little liking

Prof Calkins has now published—including this second edition of the third—no less than four text-books of protozoology · and this is a record No other man has produced so many, single-handed. In 1901—when he was but thirty-two years of age—he gave us "The Protozoa", in 1910, "Protozoology", and in 1926 and 1933 his two versions of "The Biology of the Protozoa". All these works are genetically connected, and together they give us a rough picture of their author's protozoological progress. Their titles alone suggest his steady advance from the definite and concrete into the abstract and obscure.

This can also be shown in other ways. For example, in 1901 Calkins believed whole-heartedly that all Protozoa are "unicellular organisms". Apparently he does so still, but he now finds it necessary to qualify this definition and say that they are organisms "*usually* consisting of a single cell" [italics not in original]. but as this quibble clearly cannot evade the real difficulty, he attempts to safeguard himself by adding that "As organisms the Protozoa are more significant than as cells" (whatever that may mean), and to forestall the obvious rejoinder he roundly alleges that those of us who reject the cell-theory, as applied to the Protozoa, do so merely "through sophistry" Surely the *boot* is on the other foot

In his preface to the original edition (1926), Calkins indicated his general views more fully than he does now He drew a novel distinction between "Protozoa-study" and "Protozoology" as a science, and expressed a hope that his new presentation of the subject might convert the first into the second "The underlying biological principle in this presentation," he wrote, "is the irritability of protoplasm, combined with protoplasmic organization. . . Each such organization, under appropriate stimuli undergoes differentiation through which the derived or visible organization is developed from the fundamental organization Through irritability of protoplasm and reactions to internal stimuli arising through metabolic activities as well as through reactions to external stimuli, the fundamental organization is progressively changed"—and so on, in the same strain But protozoologists—like protozoa—consist of "protoplasm" and are therefore irritable. and some of us, at least, believe that what our science really needs most at present is more "Protozoa-study" and less "Protozoology" (in Calkins's sense) We want more facts, and fewer generalities and obsolete platitudes We have no use for discussions about "the senescence of protoplasm" and similar fossils, because we regard all such antiquities as products of bad bacteriology and worse logic

No one man can now compose an accurate and comprehensive treatise on protozoology in all its manifold ramifications Prof Calkins has been attempting this impossible task—for our instruction and diversion—during more than thirty years, and though some English protozoologists dispute his knowledge and general notions, and few of us share his particular affection for *Paramecium* and *Uroleptus*, we can all admire his courage and feel grateful to him for his persistent presentation of the tenets of his own peculiar sect in America

CLIFFORD DOBELL

Towards a Planned Society

(1) *Education for Industry and Commerce in England.* By A Abbott Pp xiv + 228 (London Oxford University Press, 1933) 5*s* net

(2) *The Anti-Slum Campaign* By Sir E D Simon Pp viii + 206 (London, New York and Toronto Longmans, Green and Co, Ltd, 1933) 2*s* 6*d* net

(3) *Product Money a Sequel to 'Riches and Poverty'* By Sir Leo Chiozza Money Pp xv + 172 (London Methuen and Co, Ltd, 1933) 5*s* net

(4) *Science and Democracy adjusting the Laws of Advancing Mechanization to the Objectives of Civilized Policy* By Frank Trinca Pp v + 202 (Melbourne Brown, Prior and Co, Pty, Ltd, 1933)

THE four volumes under review deal with diverse subjects, but each subject is regarded from essentially the same angle—its place in a planned society and the contribution of science to those many vexed problems with which the advent of power production confronts our age

(1) Technical education in Great Britain has in recent years had no abler expositor than Mr A Abbott, who in this volume gives us not only an admirable yet concise historical review of the development of commercial and technical education during the last century, but also a lucid statement of the present position and an eloquent plea for the framing and carrying out of a definite policy of recruitment and training for the personnel of industry and commerce In his view, two main tasks now confront us First, the conversion of the present secondary school into a more flexible instrument for the common welfare, and secondly, the correlation of our system of technical education with our methods of general education and with the needs of industry and commerce

Both tasks call for a much closer co-operation between industry, commerce and education If the secondary school by modification of its curriculum is to become a more suitable basis for the vocational education of the technical school, it must equally remain at all costs a place of general education, and Mr Abbott does well to direct attention to the dangers of the present examination system in this respect Equally he stresses the bearing of technical education on industrial efficiency and the restoration of our lost prosperity or maintenance of our higher standard of living He makes the trenchant comment that the inefficiency of some industries is due to their failure to utilise the scientific knowledge now available for them, because they do not employ enough men with the necessary wide and thorough scientific training, and he observes that in many branches of industry there is no real hope of applying, on any adequate scale, the new knowledge gained by the various research associations, until the qualifications of the men at the top have been improved The changing nature of industrial skill, which now demands considerable intelligence, a sound general education, a willingness to develop fresh interest and an ability to adapt oneself easily and completely to fresh tasks, enforces the pressing need for a policy of recruitment deliberately conceived by every industry, with this policy should be associated a definite plan of training and promotion in which the exact function to be exercised by the schools has been determined.

With this wide vision and emphasis on a definite policy, the individual aspect is not forgotten. On the contrary, the problems which arise from the decreased vertical mobility of labour are one of the grounds on which a considered policy of recruitment is urged, and the whole book is equally a plea for planned industrial and commercial education, and for an educational system which guarantees to our children expert and sympathetic guidance in choosing a profession and adequate training for its skilled practice The problems of technical education are well and fairly stated, and the book has just claims on the attention of every scientific worker who is concerned with the future of industry and commerce

(2) Sir E D Simon writes as an acknowledged authority on housing, but his book claims the attention of scientific workers as much for its clearly sounded call for national planning in this important field as for its lucid and readable description and analysis of the present housing situation He sees the necessity for what he describes as a 'new type of politician, who

is able to come to a scientific conclusion on matters where his emotions or party interest are involved, and he deplores the weakness of our present party system that, in such matters as housing, each side prefers to urge a distorted version of the facts which suits its own prejudices rather than to ascertain the truth He does more, however, than sound a warning as to the disastrous consequences which flow from a two-party system when each party as it comes into power spends its energy in such fields in reversing the plans of the other

Sir E D. Simon gives us the outlines of a national plan, which includes the provision of an adequate statistical department to prepare the estimates on which a scientific housing problem could be elaborated to meet the real needs of the population. It would include a strong technical department, comprising a research section and taking stock of the needs of the tenant, methods of municipal management, the construction and design of houses and tenements, etc, and a planning department covering planning in all its aspects—the estate, the city, the region and the country as a whole as well as the movements of population and industry The mere enumeration of the essential activities indicates the many gaps which exist in our present knowledge and the inadequacy of our present attack on the problem

The author states a masterly case for a Ministry of Housing or a National Housing Board, which could render services in elaborating new policies and guiding and helping local authorities comparable with those rendered by the Board of Education in its own field It is obvious that he has himself a definite policy conceived on scientific lines, and it is urged with a reasonableness and an emphasis on practical issues which heartily commend it to the scientific worker

(3) Sir Leo Chiozza Money faces the problems with which science confronts society and makes a bold plea for a planned economy His explanation of the arrangement for the exchange of commodities which he describes as "product money" leaves the reader with many unanswered questions in his mind. His explanation is indeed merely a sketchy outline of his proposals, and much of the book is only a restatement of familiar criticisms of the existing credit and currency system. He is much more convincing in his exposition of the inadequacy of present exchange methods to cope with the increasingly rapid expansion of machine production, than in the presentation of his own proposals for the abolition of a circulating medium and the substitution of his product money—"a non-circulating order upon production"

The value of the book lies rather in the outlook, which refuses to accept the present unsatisfactory situation and seeks to find other and adequate methods of solving the problems of production, distribution and exchange

(4) Mr Trinca's essay in the same field is a somewhat disappointing effort. He endeavours to trace in turn the relations of science and industry, the limitations of the machine and the bearing of machine production on employment and finance, and finally the relation of industry to the wider background of economic and social life At the outset he lays a good deal of stress on what he terms the wave-law of inventive progress, but without giving adequate evidence in support of his point, nor does he allow sufficiently for the lessening place of invention in modern industry as a result of the teamwork implicit in industrial research under present-day conditions Mr Trinca handles an interesting theme, another attempt to bring scientific thought to play in every department of life, but this book is marred by so much jargon and careless writing that he is sadly open to the charge of having something to say but not knowing how to say it

R BRIGHTMAN

The Natural Resins

Die Harze Die botanischen und chemischen Grundlagen unserer Kenntnisse uber die Bildung, die Entwicklung und die Zusammensetzung der pflanzlichen Exkrete Bearbeitet von A Tschirch und Erich Stock Dritte umgearbeitete Auflage von A Tschirch *Die Harze und die Harzbehalter* Band 1 Pp xv+418 (Berlin Gebruder Borntraeger, 1933) 47.25 gold marks

THE natural resins continue to increase in economic importance notwithstanding the competition from synthetic materials, and they are the subject of monographs in several languages Prof Tschirch is one of the pioneers in the field and his book has long been a standby for those seeking information This, the third edition, has been completely rewritten with the assistance of E Stock; it covers, as explained in the sub-title, the botanical and chemical basis of the knowledge of the formation, development and composition of the plant excretions. The volume before us contains the general principles of the subject, subsequent volumes being devoted to the individual resins; it is divided into morphological, physical and chemical sections following a lengthy chapter on the formation of the exudates. This first chapter is copiously illustrated both with microscope drawings of cell structure and with photographs of the trees showing the method of collecting; it includes one fine plate in colours illustrating the fluorescence analysis of balsams and resins in the quartz lamp. The thorough and exhaustive nature of these sections which characterise the resins are exemplary.

The chemistry chapter commences with a section some hundred pages in length detailing the historical development of this special inquiry. It starts back in the sixteenth century with recollections of amber, which incidentally gave the name to electricity, and may be traced through the period of qualitative investigation in the eighteenth century and of quantitative study in the early nineteenth from the days of Unverdorben to those of Hlasiwetz. Dry distillation and fusion with alkali were among the processes summoned to help, and protocatechuic acid and phloroglucinol were recognised as important constituents. The application of newer methods to the inquiry largely begins with Tschirch's own work, commencing in 1886. The whole is a story of profound interest to the expert and the value of the section is enhanced by the copious references to the original literature from 1661 onwards; few subjects can have been more thoroughly monographed on the chemical side.

The problem of the resins is far from solved; like other complex polymers of high molecular weight, such as starch and the proteins, they are mixtures—a point emphasised by Tschirch.

The chemical section describes the generalities; the details of each resin will follow in the subsequent volumes. E. F. A.

Short Reviews

A Modern Outline of Evolution. By George Whitehead. Pp. vii+324. (London: John Bale, Sons and Danielsson, Ltd., 1933.) 7*s.* 6*d.* net.

MANY books on organic evolution written by scientific men famous for their researches are suitable to students but not to the public, who do not desire more than passing references to the facts and the general outline of theories. The book before us has no illustrations; it is reasonably cheap and as it nowhere labours, it is comfortable reading. It thus should be a useful guide to those who wish to understand 'the complex manifestations of life'. It is frankly a compilation, the story of the origin of the earth leading up to that of life. Evidences of evolution are next given and then the theories as to how it comes about, suitably ending up with a chapter on vitalistic evolution. Unfortunately there is a certain lack of understanding of the physiology of animals, function and anatomy being two inseparable factors. The chapter on Kropotkin's 'mutual aid' seems a curious and unnecessary interpolation between Darwin and Weissmann, and that on "Mutations and Mendelism" should in our opinion be entirely rewritten.

There can be no clear differentiation in the reader's mind between fluctuations and mutations, and the author's references to the opinions of those who are not researchers in this field are often valueless. The term 'character' or 'characteristic' has a clear meaning, and why it is stated that only about seven such "can be found" in the pea is extraordinary, since recent research suggests that all characters are Mendelian, and more than 400 characters have been determined in *Drosophila*.

Further, no book on evolution can be regarded as complete which does not give some account of recent research on genes, hereditary structural units responsible for every transmissible character. This is now the chief field of research leading up to the understanding of the mechanics of organic evolution, and one which the author need not fear to summarise in his second edition.

Dr. H. G. Bronns Klassen und Ordnungen des Tierreichs. Band 4, Abt. 2, Buch 2: *Acanthocephala.* Bearbeitet von A. Meyer. Lief. 1. Pp. 332. 39.60 gold marks. Lief. 2 (Schlusslieferung). Pp. vi+333–582. 32 gold marks. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1932–1933.)

DR. MEYER gives an interesting historical account of the Acanthocephala from their discovery by Leeuwenhoek (1695) who found two species in the gut of the eel. Koelreuther (1771) and O. F. Muller (1776), who independently recognised that these worms were different from other helminthes, named the first two genera, *Acanthocephalus* and *Echinorhynchus*. Bremser (1811), who is stated to have examined 40,000 individual animals for the presence of Acanthocephala, and Rudolphi, whose published accounts extend over the period 1795–1820, added much to our knowledge of these parasites. Westrumb produced in 1821 the first monograph of the group, which included a description of 90 species and an account of the anatomy and physiology. Leuckart (1862) initiated the studies on the life-history, and various writers, including the author, have developed the systematics of the group.

The historical account is followed by the systematic consideration of twelve families, 58 genera and 258 species and by an admirable description of the external features, biology, anatomy and development. In a short chapter of ten pages the damage caused by these worms in fish and domestic animals and in man is considered. Tables are given showing the hosts, both invertebrate and vertebrate, of Acanthocephala, and the geographical distribution of the genera and species. A key for distinguishing the genera, a detailed bibliography and three indexes (author, systematic and structural) are added The illustrations, 382 in the text and one plate, are well chosen and excellently reproduced, and the work forms an admirably planned and executed monograph

Handbuch der physikalischen und technischen Mechanik Herausgegeben von Prof Dr F Auerbach und Prof Dr W Hort Band 7 *Grenzgebiete der technischen und physikalischen Mechanik* Lief 1. Pp iv+238 Lief 2 Pp vi+239–490. Lief 3 Pp vii+491–814 Lief. 4: *Alphabetisches Sachregister zu Bande 1–7.* Pp xv+815–853 (Leipzig Johann Ambrosius Barth, 1928–1931) 72 gold marks

The appearance of vol 7 completes the publication of this great handbook of physical and technical mechanics (the successor to the famous Winkelmann's "Handbuch der Physik") Publication has proceeded at intervals since 1927, and previous parts have already been briefly reviewed in NATURE The present volume is devoted to border-line branches of mechanics Its articles and their authors are as follows capillarity (Auerbach, 168 pp.), capillary chemistry (Freundlich, 19 pp), disperse systems and the Brownian motion (Fürth, 40 pp), thermodynamics (Auerbach, 48 pp), kinetic theory of gases (Auerbach, 52 pp), statistical mechanics (Furth, 48 pp), fluctuations (Furth, 32 pp), theory of solid states (Braunbek, 38 pp), atomic mechanics (Joos, 33 pp), constitution of matter (Bennewitz, 27 pp.), chemical status and dynamics (Bennewitz, 34 pp), adsorption (Bluh, 42 pp), technical application of adsorption (Berl and Andress, 20 pp), the flotation process (Berl and Schmitt, 20 pp), diffusion without dividing walls (Fürth, 70 pp), osmosis (Furth, 35 pp), technical applications of electro-osmosis (Berl and Andress, 8 pp), solutions (Furth, 46 pp), electro- and magneto-mechanics (Auerbach, 20 pp) An alphabetical subject index to the whole of the seven volumes completes the work

Plant Ecology : for the Student of British Vegetation By Dr. William Leach (Methuen's Monographs on Biological Subjects.) Pp vii+104 (London Methuen and Co , Ltd , 1933) 3*s*. 6*d* net

The increasingly prominent position occupied by habitat factors in modern ecological work is reflected in this book, more than half of which is devoted to a discussion of climatic, physiographic and biotic factors and the methods employed in their practical investigation A particularly large section is devoted to soil problems and, having regard to their all-important ecological influence in Great Britain, this section should prove one of the most acceptable features of the book

The sections dealing with biotic factors and plant succession are well done, the numerous examples illustrating clearly their mode of operation in specific plant communities A chapter is given to the practical side of the subject in which directions are given for mapping vegetation, quadrat and transect observations, and estimating water content, organic matter and hydrogen ion concentration of soils The book concludes with a short account on broad lines of the principal present-day types of British vegetation and of the post-Glacial changes which have occurred as revealed by peat investigations

Diseases of the Heart described for Practitioners and Students By Sir Thomas Lewis (Department of Clinical Research, University College Hospital, London) Pp xx+297 (London . Macmillan and Co , Ltd , 1933) 12*s* 6*d* net

The name and reputation of the author of this book are sufficient guarantee of the accuracy of its contents and the wisdom of its teaching , but what makes it particularly attractive is its unusual arrangement, which is that of disorders of cardiac function, rather than of diseases of the heart The distinction is no small one , a patient's heart concerns him only in its degree of competence to carry out its work , that this aspect should be the main concern of the physician is the basis of Sir Thomas Lewis's teaching, and one of the best features of his book is its departure from the traditional arrangement of "diseases of the pericardium, of the muscle, of the valves", preceded by the stock "anatomy and physiology" If any practitioner tends to forget that his work is to treat patients, not diseases, this book, and in particular a certain half-dozen paragraphs in the last chapter, will provide the reminder

Epidemiology, Historical and Experimental the Herter Lectures for 1931 By Major Greenwood Pp x+80 (Baltimore, Md The Johns Hopkins Press , London . Oxford University Press, 1932.) 9*s*. net

In this little book are reproduced the twentieth series of the Herter lectures, delivered in 1931 by Prof Major Greenwood The first lecture is historical, the second describes a biological experimental study of epidemics, and the third considers the subject of immunity The biostatistical method of investigating disease in experimental communities leads the author to some interesting conclusions relating to the influence of the introduction of non-immune members into a herd , and although it does not yet contribute any suggestion to the problem of controlling epidemics, its more extended application may indicate the means by which real progress can be made.

The New Hydrogen*

By THE RIGHT HON LORD RUTHERFORD, O M, F R S

FOR more than a century scientific men believed with confidence that pure water was a well-defined chemical substance, H_2O, of molecular weight 18. This belief was shown by the fact that the unit of mass, the kilogram, consisting of a cylinder of platinum-iridium, was initially chosen to be of the same mass as 1,000 cubic centimetres of water at the temperature of maximum density. Subsequent measurements showed that this was slightly in error, so that the unit of mass was defined in terms of the metal standard. It was only about four years ago that this confidence was slightly disturbed as a result of the study of the isotopic constitution of oxygen. Instead of being a simple element of mass 16, oxygen was found to contain in small quantity isotopes of masses 17 and 18. It was clear from this that pure water must contain some molecules of weight 19 and 20 as well as the normal 18. Since, however, it seemed very unlikely that the proportion of the isotopes could be sensibly changed in the processes of preparation of pure water, this result, while of much theoretical interest, did not appear to have any practical importance.

As a result of investigations during the last two years, there has been a revolutionary change in our ideas of the constancy of the constitution of water. This has resulted from the discovery that a hydrogen isotope of twice the normal mass is always present in preparations of ordinary hydrogen. While this isotope of mass 2 exists only in small proportion—only about 1 in 6,000 of the main isotope of mass 1—yet, on account of the marked difference in mass of the two components, the relative concentration of the two isotopes can be varied in a marked way by various physical and chemical processes. This is seen by the fact that we are now able to obtain preparations of water in which the isotope of hydrogen of mass 1 is completely replaced by the isotope of mass 2. The density of the heavy water is about ten per cent greater than ordinary water; while its freezing point is 3·8° C, and its boiling point 1·42° C, higher. Though in outward appearance this heavy water resembles ordinary water, yet in general its physical and chemical properties show marked differences. Not only does the vapour pressure vary markedly from the normal, but also the latent heat is considerably higher. Both the surface tension and specific inductive capacity are lower while the viscosity is much greater.

It is of interest to indicate briefly the almost romantic history of this rapid advance in knowledge, and to note that there are certain points of analogy between the discovery of heavy hydrogen and the discovery of argon in the atmosphere by the late Lord Rayleigh. In both cases the clue to the discovery depended on the recognition of the importance of small differences observed in accurate measurements of density.

When the relative abundance of the isotopes of oxygen was first measured, Birge and Mendel showed that there was a slight discrepancy—only about 1 in 5,000—between the ratio of the masses of the atoms of hydrogen and oxygen measured by Aston by the method of positive rays and the ratio deduced by direct chemical methods. They concluded that this small difference was greater than the probable experimental error in the measurements and in explanation suggested that hydrogen might contain in small quantity—about 1 in 4,000—an isotope of mass 2. Let us consider for a moment how the presence of such an isotope could be demonstrated by direct experiment. Both the H^1 and H^2 isotopes would have the same nuclear charge of 1, and have one external electron, and would thus be expected to give the same type of optical spectrum under the influence of the electric discharge. It is to be remembered, however, that the electron, the movements of which when disturbed give rise to its characteristic radiations, is coupled to the nucleus, and that the rates of vibration, although mainly governed by the nuclear charge, are slightly affected by the mass of the nucleus itself. On account of the greater mass of the H^2-isotope, it can readily be calculated that the Balmer lines in the spectrum of heavy hydrogen should appear slightly displaced towards the red. In the case of the α line, the displacement amounts to 1·78 angstrom units. When an electric discharge is passed through ordinary hydrogen, weak satellites should thus appear on the side towards the red. The presence of such weak satellites in the right position was first detected in experiments made for the purpose by Urey, Brickwedde and Murphy. The intensity of the satellite compared with the strong H_α line was difficult to measure with certainty but was found to be of the order of 1 to 5,000.

Experiments were then made to enrich the H^2 isotope by fractional distillation of liquid hydrogen, and with some success. Another important observation was made by Urey and Washbourn, who found that the water in old electrolytic cells contained a larger proportion of heavy hydrogen than the normal. The concentration of H^2 was found to be rapidly enriched by continued electrolysis. This gave the key to a successful method of obtaining heavy hydrogen in quantity. The processes involved were carefully investigated by Lewis and Macdonald, and the electrolysis of water was carried out on a comparatively large scale. Nickel electrodes were used, and sodium hydroxide as an electrolyte. In general, it was found that the escape of H^1 during electrolysis was five to six times faster than that of H^2 relative to their concentrations in the solution. There was in consequence a steady accumulation of the heavy isotope in the water in the process until nearly pure heavy water was obtained Assuming that the initial concentration of H^2 in the water was 1 in 6,000, about 1 c c. of pure heavy water should be obtained by electrolysis of 6 litres of water

---

* Discourse delivered at the Royal Institution on Friday, March 23.

Lewis succeeded in preparing many cubic centimetres of heavy water in which ordinary hydrogen was present in very small quantity He and his collaborators investigated the main physical and chemical differences between heavy water and ordinary water, to some of which I have already referred Our congratulations are due to our American colleagues for the masterly way they have opened up and developed so rapidly this new field of knowledge, which it is certain will prove of great scientific and practical importance in many directions in the near future Prof G N Lewis, of the University of California, who was the first to prepare nearly pure heavy water, generously presented samples of this water to a number of investigators, not only in his own country but also in Europe, in order to give them an early opportunity of testing its properties I am personally much indebted to Prof Lewis for a sample of this heavy water with which we were able to make a number of experiments on the transformation of matter to which I shall refer later

We are all aware of the important part that hydrogen plays in many chemical compounds and particularly in organic molecules When reasonable supplies of heavy water are available to the experimentor, there will no doubt be great activity in preparing and studying many compounds in which H^1 in the molecule is wholly or partly replaced by H^2 Already a few investigations have been carried out, for example, with ammonia and with hydrogen iodide, in which H^1 is replaced by the heavy isotope It has been found that in mixtures of light and heavy hydrogen gas, the atoms interchange on a nickel surface at a temperature of about 600° C and the conditions of equilibrium and heat evolution have been investigated. During the next few years we may expect an intensive study to be made of the change of properties of compounds in which heavy hydrogen is used It will be of particular interest to examine the changes in the rates of reaction at different temperatures when heavy hydrogen is substituted for ordinary hydrogen

The discovery of the new water will be of great importance in another direction, namely, its effect on the processes occurring in animal and plant life There has not yet been sufficient time to make more than a few preliminary experiments in this field, and then only on a small scale. Lewis finds that seeds of a certain tobacco plant did not germinate in pure heavy water but did so when the concentration of heavy hydrogen was about one half In experiments by other observers, well-defined physiological effects have been obtained for quite small concentrations of heavy hydrogen in water. Further observations in this highly important field of inquiry will be awaited with much interest

It is widely recognised that the new hydrogen will prove of so much general importance to chemistry and physics that it is desirable to give it a definite name and symbol Prof Urey, its discoverer, has suggested that the isotope of mass 1 should be called 'protium' and the isotope of mass 2 'deuterium', while the nucleus of heavy hydrogen, which has already been found very efficient as a projectile in transforming matter, should be called 'deuteron' or 'deuton' The question of a suitable nomenclature is one of general importance to scientific men and deserves careful consideration The name 'diplogen' (διπλους, double) for H^2 and 'diplon' for the nucleus seemed to find some favour in England as an alternative The symbol D for the heavy isotope seems appropriate

While diplogen (or deuterium) may be separated in quantity from heavy water in nearly a pure state, it is of interest to refer to another method of separation employed by Hertz By utilising a special diffusion method devised by him, he has been able to separate from ordinary hydrogen gas about 1 c c of diplogen in such purity that the Balmer lines of hydrogen were not visible in its spectrum With such pure material, it should be possible to study in detail the complicated band spectrum of diplogen and compare it with that of hydrogen

We have not so far considered the question of the nuclear structure of diplogen and its relation, if any, to that of ordinary hydrogen We first of all require to know its mass with accuracy, this has been measured by Bainbridge by using a modification of the positive ray method, who found that the mass of the atom is 2 0136 while the mass of the hydrogen atom is 1·0078 in terms of the mass of the main isotope of oxygen taken as 16 This mass is slightly less than the combined mass of two H atoms Sufficient evidence is not yet available to decide whether the D nucleus is simple or composite, and there are a number of possible combinations to consider between the four units, the electron, positron, neutron and proton If we assume, as seems not unlikely, that the D nucleus consists of a close combination of a proton with a neutron, it can be shown from the masses concerned that its binding energy should be somewhat less than 1 million volts if we take the value 1 0067 for the mass of the neutron as estimated by Chadwick If this be the case, we should expect the diplon to be broken up occasionally into a proton and neutron as a consequence of a close collision with a fast α-particle. Experiments to test this have so far yielded negative results If this dissociation occurs at all, the probability of such an event must be very small Lawrence, from a study of the bombardment of elements by diplons, suggests that the diplon may break up into a proton and neutron in the strong electric field close to the bombarded nucleus, but the interpretation of his results is not yet certain At the moment, therefore, the experimental evidence is insufficient to give a definite decision with regard to the structure of the diplon

By comparing the scattering of α-particles when passing through diplogen and hydrogen gas, Mr. Kempton and I have found that as the result of a head-on collision with an α-particle, the recoiling diplon travels about eight per cent farther than the proton in a corresponding collision Such a result is in agreement with calculation It also seems clear that the field of force round the diplon must be very similar to that of the proton, although it may be expected that some differences would be shown for very fast α-particles if the diplon is composite as we have supposed

TRANSMUTATION OF ELEMENTS

The discovery of heavy hydrogen has provided us with a new form of projectile which has proved markedly efficient in disintegrating a number of light elements in novel ways It was a very fortunate coincidence that, when Prof Lewis had prepared some concentrated diplogen, his colleague in the same University, Prof Lawrence, had available his ingenious apparatus for producing high-speed protons and other particles with an energy as high as two million volts When diplogen was substituted for hydrogen, the diplon (D^+) was found to be about ten times as efficient in promoting some transformations in lithium as H^+ of equal energy It will be remembered that Cockcroft and Walton found two years ago that lithium, when bombarded with fast protons, was transformed, with the emission of swift α-particles It seems clear that in this case the lithium isotope of mass 7 is involved A proton is captured by the nucleus and the resulting nucleus breaks up into two α-particles, ejected in nearly opposite directions, according to the relation

$$\mathrm{Li}^7_3 + \mathrm{H}^1_1 \rightarrow \mathrm{He}^4_2 + \mathrm{He}^4_2$$

The emission of other particles of short range has also been observed but the exact nature of the transformation which gives rise to them is not yet clear

When lithium is bombarded with diplons instead of protons, different types of transformation occur In one case it seems that the lithium isotope of mass 6, after capturing a diplon, breaks up into two α-particles according to the equation

$$\mathrm{Li}^6_3 + \mathrm{D}^2_1 \rightarrow \mathrm{He}^4_2 + \mathrm{He}^4_2$$

In this case also, as has been shown beautifully by the expansion photographs obtained by Dee and Walton, the two α-particles are shot out in opposite directions and with a speed greater than the swiftest α-particle from radioactive substances

Still another interesting type of complex transformation occurs in this element. Oliphant and Rutherford observed that lithium when bombarded by diplons gave, in addition to the group of fast α-particles first observed by Lawrence, a distribution of α-particles of all ranges from 7·8 cm to 1 cm in air. It is believed in this case that the isotope of mass 7 captures a diplon and then breaks up into two α-particles and a neutron according to the relation

$$\mathrm{Li}^7_3 + \mathrm{D}^2_1 \rightarrow \mathrm{He}^4_2 + \mathrm{He}^4_2 + n^1_0$$

This transformation is in close accord with the conservation of energy when the change of mass and the energies of the expelled particles are taken into account The emission of neutrons from lithium has been observed by Lauritsen and also in our experiments In addition, Lawrence has shown that a number of other light elements give rise under bombardment to groups of fast protons and in many cases also to α-particles and neutrons While the interpretation of the experimental results is as yet only clear in a few cases, there can be no doubt that the use of heavy hydrogen will prove invaluable for extending our knowledge of transformations and thus in helping to throw light on the structure of atomic nuclei

The importance of this new projectile in studying transformations is well illustrated by some recent experiments made in Cambridge with Oliphant and Harteck When diplons were used to bombard compounds like ammonium chloride, NH_4Cl, and ammonium sulphate, $(NH_4)_2SO_4$, in which ordinary hydrogen was in part displaced by diplogen, enormous numbers of fast protons were found to be emitted, even for an accelerating voltage of 100,000 volts In fact the number of expelled particles is far greater than that observed in any other type of transformation at this voltage The main groups of expelled protons had a range in air of 14 cm, corresponding to an energy of 3 million volts In addition to this group, another strong group of singly charged particles were observed of range in air only 1 6 cm Both of these groups contain equal numbers of particles

In order to account for these observations, it seems likely that, as the result of a close collision, the diplon occasionally unites with the struck diplon to form a helium nucleus of mass 4 and charge 2, but containing a large excess of energy over the normal helium nucleus The new nucleus is in consequence explosive and breaks up into two parts, one a fast proton and the other a new isotope of hydrogen H^3_1 of mass 3 If this be the case, the proton and H^3 nucleus should fly apart in opposite directions It can be simply calculated that the range of the recoiling H^3 nucleus under these conditions should be 1·7 cm—a range agreeing closely with that actually observed The changes occurring are illustrated by the equation

$$\mathrm{D}^2_1 + \mathrm{D}^2_1 \rightarrow \mathrm{He}^4_2 \rightarrow \mathrm{H}^3_1 + \mathrm{H}^1_1$$

From the known masses of D and H^1 and the energy of the observed motion of the H^1 and H^3 particles, it can be deduced that the mass of this new hydrogen isotope is 3 0151

In these experiments, large numbers of neutrons are also emitted It appears probable that these arise from another mode of disintegration of the newly formed helium nucleus according to the relation

$$D_1^2 + D_1^2 \rightarrow He_2^4 \rightarrow He_2^3 + \text{neutron},$$

an isotope of helium of mass 3 and a neutron being expelled in opposite directions. There is strong evidence that such an isotope of helium also appears when the lithium atom of mass 6 is bombarded by protons, and from this transformation it appears that the mass of this isotope is 3 0165 It is quite likely that the helium nucleus of mass 3 formed in this way is unstable and may possibly break up into H_1^3 and a positive electron While the conclusions outlined above are to some extent provisional and require confirmation by other methods, there can be no doubt that the effects which follow the collisions of a swift diplon with another are of much importance and interest in throwing light on possible modes of formation of some of the lighter nuclei

It is of interest to speculate why the heavy isotope of hydrogen appears in many cases far more effective, for equal energies, in producing transformations than the lighter isotope On the general theory of transformation proposed some years ago by Gamow, it is to be anticipated that, for equal energies of motion, the diplon on account of its heavier mass would have a smaller chance of entering a nucleus than the swifter proton It may be, however, that normally only a small fraction of the protons which actually enter a nucleus are able to cause a veritable transformation, the others escaping unchanged from the nucleus On this view, the greater efficiency of the diplon in causing transformation may be due to the fact that a much larger fraction of those which enter the nucleus are retained by it, leading to a violent disintegration of its structure It may be too that the diplon on entering a nucleus breaks up into its component parts The appearance of the proton as well as the neutron in some of the transformations may be connected with the composite structure of the diplon.

Deep Water Circulation of the Atlantic

DR G. WÜST, oceanographer in the German research vessel *Meteor*, has recently published the first part of vol 6 of the reports of the German Atlantic expedition* The report is not only a description of the *Meteor*'s results, but is also a history of the investigation of the Atlantic deep waters, and gives a critical summary of all the observations that have been made from those of H M.S. *Challenger* (1873–1876) to those of the R R.S. *Discovery II* (1929–1931) At the end of the report is a complete list of the observations used

Dr Wüst has made extensive use of the principle that if the water in a deep current sinks to a lower level, its temperature will increase as the water becomes adiabatically compressed, and conversely, that if the deep current rises, the water in it is cooled owing to adiabatic expansion Any attempt to follow the path of a deep current in a vertical section showing temperature distribution is made much more difficult by these changes It was first suggested by Prof Helland-Hansen that the difficulty should be removed by using vertical sections showing the distribution of potential temperature—the temperature to which the water would be cooled if it were raised adiabatically to the surface. This report is a striking tribute to the advantage of this method.

In the report there are charts showing the actual temperature, the potential temperature, and the salinity of the bottom water (at depths greater than 4,000 metres) over the whole of the Atlantic Ocean There are also vertical sections which show the distribution of potential temperature, and salinity, along the east and west Atlantic basins, on either side of the mid-Atlantic ridge With their help, Wust shows that the flow of antarctic and arctic bottom waters is much more asymmetrical than it was thought to be Antarctic bottom water flows northwards along the sea bottom, mixing with the warmer North Atlantic deep water which is flowing southwards above it The last traces of the antarctic water reach as far as 34° N in the east Atlantic basin and to 40° N in the western basin. The influence of bottom water of arctic origin can only be detected north of these latitudes as a very weak current

From the relations between potential temperature and salinity, Wüst has been able to find the percentage of antarctic water at the bottom in both basins in all latitudes. These percentages are shown by two curves The decrease of the antarctic water along the western basin is almost regular, it is hastened in about 5° S. where the Para rise obstructs the bottom current In the eastern basin the northward flow is stopped at the Walfish ridge, which extends transversely from the African coast to the mid-Atlantic ridge. The antarctic bottom water north of this ridge enters the basin from the west through the Romanche channel, a break in the mid-Atlantic ridge near the equator. The bottom water flowing through this channel spreads southwards to the Walfish ridge and northwards to 34° N By means of a chart showing the distribution of potential temperature at the bottom of the Scotia Sea, based principally on the observations made by the ships of the "Discovery" Committee, Wüst has been able to show that antarctic bottom water also flows westwards into the Pacific Ocean

---

* *Schichtung und Zirkulation des Atlantischen Ozeans* Lief 1 *Das Bodenwasser und die Gliederung der Atlantischen Tiefsee.* Von Georg Wüst (Wissenschaftliche Ergebnisse der Deutschen Atlantischen Expedition auf den Forschungs- und Vermessungsschiff *Meteor* 1925–1927, herausgegeben im Auftrage der Notgemeinschaft der Deutschen Wissenschaft von A. Defant, Band 6, Teil 1) Pp 107+8 Beilagen (Berlin und Leipzig. Walter de Gruyter und Co., 1933.) 20 gold marks.

It is interesting to note that the increase in temperature of the bottom water in the direction of flow can be accounted for solely by mixing with the North Atlantic deep water No increase in temperature due to heat conducted through the earth's crust can be detected, and earlier attempts to measure the speed of the bottom current based on the assumption that the increasing temperature is the result of such conduction have been proved worthless

The vertical distribution of potential temperature far south has changed Wust s views on the origin of antarctic bottom water He now believes that the coldest water is that which is cooled right through on the antarctic shelf in winter and sinks down the continental slope This was the view held by Drygalski and Brennecke but it could not be proved, because all the observations made in the open sea show that the bottom water is always covered with a layer of warm deep water through which the bottom water cannot be seen to sink This warm layer is only absent from channels or basins adjacent to the antarctic continent which are cut off from the open sea by well defined ridges rising above the level of the layer In such basins there may be almost complete mixing from the surface to the bottom

Wüst, in attempting to find a vertical series of observations which showed the cold water from the shelf sinking down the continental slope has used a series (Deutschland St 125) in such an enclosed basin, from which the water cannot sink because of a ridge His failure to recognise this fact and the omission of the ridge makes the diagram on p 45 misleading He distinguishes a slightly warmer bottom water which he calls antarctic deep water , he believes it to be formed by the effect of strong cooling and formation of ice in autumn and winter on the surface water in a convergence region situated near the edge of the pack ice between 60° and 66° S In this theory, Wust appears to be making a determined attempt to bring the views which he and Nansen have expressed on the formation of antarctic and arctic bottom water into accord with the known data regarding the circulation of the Weddell Sea There is very little reason for believing that a convergence region exists, the deep water is probably bottom water which upwells in the middle of the cyclonic movement

Wust has shown that there is very close agreement between the distribution of antarctic bottom water and the distribution of sediments poor in calcium (particularly the red clay) North of 34°–36° N where the streams of antarctic water die away, the bottom deposits are no longer poor in calcium The antarctic water dissolves calcium and over each of these poor deposits it has been found to be enriched The report shows that in such places the density of the water calculated from the usual chlorinity ratio is too low By means of sections giving the distribution of potential density, it is shown that the density of antarctic bottom water calculated from the usual ratio is less than that of the North Atlantic deep water This is because there is a chlorine deficit in the bottom water, or as there is some reason to believe, a chlorine excess in the North Atlantic deep water Wust points out that there is a pressing need of accurate physical and chemical determination of these small density differences, and of new tables and methods for the practical determination of density and salinity and the correction of densities calculated from chlorine contents G E R D

Obituary

DR F A BATHER, F R S

FRANCIS ARTHUR BATHER, born in 1863 was the eldest son of the late Mr A H Bather From Winchester he gained a scholarship at New College, Oxford, where he graduated in 1886, taking first class honours in natural science In 1887 he entered the Department of Geology in the British Museum (Natural History), where his care was chiefly the fossil echinoderms, and notably the crinoids In 1892 he gained the Rolleston prize of the Universities of Oxford and Cambridge for research in biology His first scientific publication of importance was on the Crinoidea of Gotland, in 1893 He was married at Stockholm in 1896, and in 1897 he was awarded the Wollaston fund of the Geological Society On the retirement of Dr Henry Woodward in 1902, Dr Bather was appointed deputy-keeper, a position which he held until 1924, when he assumed the keepership vacated by Dr (now Sir) Arthur Smith Woodward He was elected fellow of the Royal Society in 1909, and in 1911 was awarded the Lyell medal of the Geological Society and served as president of that body in 1926–28 He was also a member of several foreign scientific societies Retiring from the Museum in 1928, he still visited the Department of Geology to pursue his researches on crinoids which had been seriously interrupted by his administrative duties as deputy keeper and keeper Though failing in health during the past year he was active until the last, and when after two days' illness he passed away on March 20, the sad news came as a shock to his many friends

Such, in bare outline, was the professional career of one whose many sidedness was continually a surprise to those who knew him and, of course, such a bald enumeration of facts can give no distinctive picture of the man, even as a professional palæontologist Nor is it always easy, in considering Dr Bather s many activities, to draw the line between his professional and other interests

The need of clear thinking in scientific researches, and of lucid exposition in scientific description, developed in him a mastery of style in writing and diction which harmonised with his appreciation of literature, and especially with his love of Shakespeare. That, in turn, found a further outlet in his dramatic talent—the practical expression of literature—just as museum 'curating' gave scope to the practical side of his scientific interest He always insisted that all who could do so should draw the illustrations for their own scientific papers, and it is not, therefore, surprising to learn that he appreciated art, and to some extent practised both drawing and painting So his many outside activities could be seen to spring from qualities which, used and developed in his professional work, demonstrated the essential harmony of his nature

More closely bound to his strictly professional work were what were perhaps the two greatest preoccupations of Dr Bather's unofficial life—museum technique and scientific journalism His chief official duties were 'curating' and identifying, and, as a wide knowledge of museum technique is obviously desirable for making a perfect curator, so research is necessary for identifying material, and the critical faculty which research engenders, easily developed in Dr Bather into a flair for reviewing and other journalistic activities It was to be expected, then, that when the Museums Association was founded, Dr Bather from the first was one of its most active supporters and inspirers and, through the *Museums Journal*, its most eloquent mouth-piece He presided at the Aberdeen conference in 1903, and his enthusiasm for the Association continued until his death His journalistic activities were widely spread Early in life he edited the periodical *Natural Science*, and for many years the *Museums Journal* Articles, notices and letters were ever flowing from his pen; but perhaps his most appreciated efforts were the delightful reviews which he wrote for the *Times Literary Supplement*

But all Dr Bather's outside interests, his zeal for museum technique, and his critical and literary talent, were subordinated to his professional work Were the foreign museums ahead of the British Museum in this respect? Corresponding improvements must be procured for the Department of Geology. Did that standard obtain in any journal or scientific publication? The Department's publications must set the standard for all outside bodies So keen was he upon the adoption of this or that improvement, even in the little things of curatorial practice, that he appeared more pleased with the appreciation shown him by the application of one of them, than by a favourable reception of his scientific papers. I know that he sometimes felt that his labours for improved curating were not fully appreciated; whereas an enumeration of the improvements, great and small, in curatorial practice introduced by him should have effectively silenced that misgiving. He has been considered to have had too great a consideration for minutiæ. Indeed, his mind marched with his who wrote —

> "Thus, if this Age but as a comma show
> 'Twixt weightier clauses of large-worded years,
> My calmer soul scorns not the mark: I know
> This crooked point Time's complex sentence clears"

Dr Bather insisted on the comma because he appreciated its relation to the whole

If his colleagues have not always appreciated as fully as Dr Bather would have liked all his curatorial 'gadgets', there is no fear of their ever under-rating the brilliance of his scientific work His clear exposition, clean style, and description couched in the most direct language, as well as his orderly presentation and accuracy of detail, are nowhere better shown than in what he himself considered his master-work—"Caradocian Cystidea from Girvan" This and his other scientific treatises are the standards to which his colleagues aspire in their own publications, and in which they recognise him as indeed a master

It was Dr Bather's expressed intention, when at last relieved of administrative duties, to resume his interrupted researches upon fossil echinoderms, and particularly crinoids It was the hope of some, at least, of his friends, that his last years would produce some masterpiece of synthetic thought dealing with the evolutionary aspects of palæontology But, when Dr Bather retired, he no longer possessed the energy needed to disengage himself from the multifarious interests which entangled him, and prevented him from resuming his studies uninterruptedly Thus we consider his life-work incomplete The larger vision may see in his widely-flung helpfulness a life better proportioned and more complete than we suppose

Dr Bather suffered fools kindly, and with humour, and if at times, like Wisdom, he led them by crooked ways and tormented them with his discipline, his patience with stupidity was remarkable, and no one who has been through his 'mill' will deny that it has been worth while to have been taught by Dr Bather how to write a paper or arrange a collection, or will fail in gratitude to him His intellectual honesty, and devotion to duty, tempered with a most kind heart, and lightened by a charitable sense of humour, indicated the quiet flow of his genius beneath a restless exterior W D LANG.

PROF. S F OLDENBURG

WE regret to record the death on February 28 at the age of seventy years of Prof. Sergius Fedorovitch Oldenburg, the well-known Russian orientalist and former permanent secretary of the Russian Academy of Sciences

Prof Oldenburg was born at Byanking in Siberia and was educated at Warsaw and the University of St. Petersburg, where he specialised in oriental languages and more particularly the Indian dialects. After graduation he was for a time engaged in research work at Cambridge His first book on "Buddhist Legends" appeared in St Petersburg in 1894 In 1895 he was appointed to the chair of Indian languages and literature in the University of St. Petersburg, which he held for thirty years His election to the Academy of Sciences in 1903 was followed in the next year by his appointment as permanent secretary of the Academy and soon after he was made director of its Asiatic Museum

At this time Germany, France and Great Britain, through Grünwedel and von Le Coq, Pelliot and Stein respectively, were engaging in a campaign of intensive archæological exploration in Chinese Turkestan Attention had been attracted to this territory by the Russian expedition under Klements in 1898 and by Sven Hedin's explorations, but the full extent of the opportunities for archæological research had been revealed only by Stein's discoveries Russia's desire to participate in this important work in the field was met by the organisation under Oldenburg's direction of an expedition of exploration to the oasis of Kucha under the leadership of Berezowski (1906–7) Later, another expedition was sent out by the Academy under Oldenburg himself, which explored Karashahr and Turfan and brought back a rich store of manuscripts, paintings and sculpture from the caves of Tung-hwang discovered by Sir Aurel Stein The results of the expedition were published in Oldenburg's valuable book, "The Russian Expedition to Turkestan" (1914 in Russian).

After the revolution of 1917, Oldenburg retained his chair and his secretaryship of the Academy for twelve years. His experience in the organisation of research both at home and in the field was of material assistance to the Soviet Government in carrying out its desire to re-establish archæological and ethnological exploration In 1929, however, he was dismissed from his posts for political reasons by the Government, but he was so far readmitted to favour that the Academy and other scientific bodies were permitted to express recognition of the celebration of his seventieth birthday

WE regret to announce the following deaths

Col Arthur Lynch, author of several original books on psychology, philosophy and relativity, on March 25, aged seventy-two years

Prof C Matignon, professor of inorganic chemistry in the Collège de France, president of the Société Chimique de France, on March 18, aged sixty-six years

Sir Thomas Muir, CMG, FRS, formerly superintendent-general of education in Cape Colony, author of works on the history of determinants, on March 21, aged eighty-nine years

Prince Sixtus of Bourbon-Parma, whose expeditions to Central Africa produced valuable scientific results, on March 14, aged forty-seven years.

Dr E W Washburn, chief chemist in the United States Bureau of Standards, on February 5, aged fifty-two years

News and Views

Petroleum in Great Britain

OCCURRENCE of petroleum in Britain is once again in the limelight, this time focused by what, from a public point of view, seems to be sudden and dramatic action on the part of the Government On March 22, the President of the Board of Trade announced in the House of Commons that the whole question of oil exploration has recently been reviewed following renewed activities in this direction It is intended to introduce legislation forthwith to remove certain difficulties existent under the Petroleum (Production) Act 1918, and to secure orderly development of any oil which may be discovered. The most far-reaching and drastic proposal is that ownership of all petroleum at present unknown shall be vested in the State A licence to explore for oil must be obtained from the Board of Trade, payment being made to the Exchequer on any oil produced. The bill was introduced in the House of Lords on March 22. In addition to the provisos mentioned above, the bill makes possible compulsory acquisition of rights to enter on land; further, that in considering any application made to the Railway and Canal Commission under that Act, the Commission shall have regard to the effect on the amenities of the locality. Compensation in respect of granting prospecting rights is to be made subject to additional allowance of not less than ten per cent on account of compulsory acquisition

OTHER clauses of the bill deal with the Board of Trade receipts and expenses in connexion with licences, payments to the Exchequer, the manner in which and persons by whom applications may be made, fees, size and shape of chosen areas, right to inspect all plans, etc., the Board throughout exercising its powers through the Secretary for Mines The opportunity was obviously one too good to be missed by certain more sensational sections of the Press, which translated what is essentially a sober, political measure into actual discovery of oilfields, one paper even going so far as to give a map depicting the 'track of the oil belt' from the Humber to Cardigan Bay! In a long experience we doubt whether British geology has ever received such flagrant affront. Aside from technicalities, it is common knowledge that the existing licences held under the Act of 1918 are in respect of Hardstoft, Derbyshire (1923), Heathfield, Sussex (1930) and Three Bridges, Sussex (1931), trial borings also being made at Hythe, Kent, in 1929. In no case have these activities attained commercial status. The drilling epic of 1918–22, a War-time measure, though forgotten by the public, is still fresh in the minds of oil technologists in Great Britain, and no Government bill, reports of foreign enterprise, secret explorations in Derbyshire or elsewhere, animates us from resignation to facts which one-time emergency and progressive geological knowledge have taught.

OIL pools of commercial magnitude (*pace* natural gas, shale oil and allied indications and potentialities) cannot reasonably be anticipated in any known area in Great Britain Many years of official geological survey—a centenary in 1935 in point of fact—together with much independent work, leave few spots unknown, if not in detail, at least in sufficient outline to preclude even faint hope The Government measure is discreetly, if not satirically, worded · it refers to oil which *might* be discovered or *may* exist, it excludes Northern Ireland from the Bill, presumably on political grounds, in this, as with the rest of Great Britain, it has the silent approbation of British geology, though it is in the public interest that that silence should be officially broken if the present bill is in any way interpreted as supporting authoritative views that oil does indeed exist in Great Britain and only awaits public money for its development.

Royal Botanic Gardens, Regent's Park

WHEN the lease of the Royal Botanic Society, Regent's Park, terminated in 1931, the grounds were thrown open to the public, but arrangements were made with the Office of Works for continuing the investigations in genetics which had been carried on there since the War This arrangement has now been placed on a permanent basis, a portion of the original Gardens, including a quadrangle of buildings and the adjacent grounds, having been set aside for this work on rental from the Office of Works Through the action of Prof R. Ruggles Gates, the Courtauld research fund of £5,000 has been obtained as an endowment for this work, which is an important extension of the research facilities of the Department of Botany, King's College. The facilities include two greenhouses with boilers for heating, a potting shed, tool house, cold frames and a laboratory of four rooms. The latter is being fitted up for the examination of genetical material and the collection and treatment of cytological material from plants grown in the Gardens, as well as for photographic work The Empire Cotton Growing Corporation is also making a grant for three years in aid of further researches on cotton and its relatives. Various other temperate and tropical economic plants are being investigated. The fundamental researches in cytogenetics, with which the name of Prof. Gates has been connected for many years, have now been extended to include a study of the native species of *Œnothera* in eastern Canada The phenomena of distribution, relationships and hybridisation of the native species and varieties (many of them undescribed) found in this area constitute a genetic survey which throws light on many phases of the complicated evolutionary problems in this genus.

Sir Charles Parsons Memorial

THE Sir Charles Parsons Memorial Executive Committee, composed of the presidents of thirteen scientific and technical societies, with the Engineer-in-Chief of the Fleet, and presided over by Sir Frederick Gowland Hopkins, has just issued a statement of its aims and an appeal for subscriptions. Observing that the name of Parsons will ever be remembered with those of Newcomen, Watt, Trevithick and Stephenson, and that his fame was due not only to his work in marine and electrical engineering, but also to his investigations in various branches of physics, the statement says that it has been decided that the memorial shall take several forms. It is proposed, first, to place a memorial to him in Westminster Abbey; secondly, to found an annual lecture to be given by a distinguished man of any nationality, who will be chosen in turn by the various scientific and technical societies; and thirdly, it is proposed to arrange with the governors of London House that the library in that House shall be called the "Parsons Research Library". A bronze medal will be established in connexion with the annual lecture and a bust of Sir Charles Parsons will be placed in the library London House was founded in 1931 as a hall of residence for Dominion and Colonial men students of white parentage, from the Empire overseas The property, now under development, covers an area of about 1½ acres in the Bloomsbury district close to the University of London, and the proposed library will contain scientific and technical works To carry out the whole scheme, it has been estimated that a sum of at least £12,000 is required Copies of the appeal are being sent to members of the societies concerned, and the Executive Committee suggests that in general the maximum subscription should be two guineas. Donations should be sent to the Royal Society, Burlington House, W 1, and cheques made payable to the "Sir Charles Parsons Memorial Fund"

The New Hydrogen

IN the course of Lord Rutherford's Friday evening discourse on March 23 at the Royal Institution (see p. 481), experiments were shown to illustrate the differences in freezing point and in vapour pressure between ordinary and heavy water, and the differences in heat conductivity between ordinary and heavy hydrogen For the first time, experiments were made to show the artificial transformation of lithium by protons and diplons of energy corresponding to about 100,000 volts The enormous emission of fast protons when ammonium sulphate containing heavy hydrogen was bombarded by diplons was clearly shown by counting methods. The transformation apparatus was designed and operated by Dr. Oliphant, while Messrs. Watson and Sons (Electro-Medical) Ltd loaned an installation to provide a steady potential of 100,000 volts to accelerate the ions

Developments of Television

AN application of science has enabled a chairman of a company to become a historic figure. At the annual general meeting of Baird Television, Ltd., held in a theatre in the west end of London on March 20, the shareholders heard and saw distinctly the chairman address them from a studio at the Crystal Palace, nearly eight miles distant. To the shareholders, and afterwards to representatives of the Press, the Baird Company arranged a programme of transmissions by radio from the Crystal Palace to enable the audience to see persons talking on various subjects, a cartoonist sketching at his easel, excerpts from popular films and 'still' pictures. All these items were reproduced in the receiver with sufficient detail for an audience of more than a hundred persons to 'look in', although the receiver was devised for use in the home rather than a theatre. The success of these demonstrations is attributed to the state of perfection of the large cathode ray oscillographs made exclusively for the Baird Co. by the research staff of a British industrial concern, the excellence of the photoelectric cells in use at the transmitting end, and the construction of amplifiers which are capable of dealing without phase distortion with a range of frequencies from 25 to 1,000,000 cycles per second. The subject matter to be televised is divided up into 180 lines (or strips) corresponding to 24 times the definition obtainable with the old 30-line apparatus. Vision is being transmitted from a dipole aerial on a wave-length of 6·0 metres, and sound on 6·25 metres.

JUDGING from the demonstrations given last week, the Baird Company's engineers have successfully overcome interference effects due to motors, lifts and other electro-magnetic disturbances met with at these short wave-lengths. A series of experiments have been carried out to ascertain the effective range of reception, as a result of which it is claimed that the Crystal Palace transmitting station can provide an ultra-short wave high definition television service for the whole of the Greater London area, which includes a population of about eight millions. Capt. A. G. D. West, who joined the board of the Baird Company last June to direct its technical development, is to be warmly congratulated on his achievement; and the Company on the first public demonstration of the broadcasting possibilities of high-definition television. We understand that a demonstration will shortly be given of the intermediate film-method, described by Major A. G. Church in NATURE of September 30, 1933, by means of which televised images of topical events will be thrown on screens in cinema theatres, as well as on home-receivers within a few seconds of their occurrence. Another series of experiments on a new system of 'scanning' invented by Mr. Baird is nearing completion. These experiments aim at securing sufficient illumination in a studio to enable 'crowd' scenes to be televised directly with detailed fidelity.

Statistics in India

IN a paper on "India's Trade and Industrial Statistics", read before the Royal Statistical Society on March 20, Sir H. A. F. Lindsay, the Government of India Trade Commissioner in London, pointed out that progress in the compilation and preparation of official statistics in India has been from departmental to expert control. In 1871, when Sir William Hunter was appointed as the first Director-General of Statistics, the local authorities submitted their statistics to the appropriate Government department, which was responsible for tabulating and publishing them. Afterwards, expert control was gradually introduced, and now the Director-General is directly responsible for compilation and review. A new series of monthly statistics recently introduced relates to the output of the more important Indian industries and includes jute manufacture, paper, cement, matches, sugar, iron and steel, kerosene, petrol, sulphuric acid and sulphate of ammonia. In addition, cotton spinning and weaving statistics have been collected and published for many years past. The main difficulty has been to obtain statistics of the output of the numerous cottage industries which exist alongside modern large-scale factories, sometimes in active competition with those factories and sometimes catering for quite a different class of consumer. The Indian factory, however, provides a useful unit for the collection, compilation and publication of statistics of industrial output, and India has made a good start in this direction. There are many countries of no little industrial importance which have not yet made comparable efforts in the sphere of industrial statistics.

Origin of Bronze

AT a meeting of the Newcomen Society held on March 21, three short papers were read. The first of these, entitled "The Origin of Bronze", was by Prof. C. H. Desch, who gave an account of the results of the inquiries made for the committee of the British Association appointed to investigate the sources of the copper used by the Sumerians. Many specimens of objects found recently at Ur, Kish, Tell Asmar and other places have been analysed, and earlier analyses have been critically examined. A striking discovery is that true bronzes were made at a very early date and some of these contain certain 'key' elements, such as nickel and arsenic. So many of the early Mesopotamian objects examined contained small quantities of nickel that a search was made for copper ores containing nickel. One ore was found, accompanied by slag, at Jabal al Ma 'adan, in the State of Oman, and there are reasons for supposing this was a source from which the Sumerian cities drew their copper. Bronze, said Prof. Desch, must have originated in the East, and for further light on its origin an examination of ores from such places as Anatolia, northern Persia and Baluchistan must be made.

Early Dredging Machine

ANOTHER paper read at the meeting of the Newcomen Society on March 21 was by Mr. G. Bathe and dealt with the dredging machine of Oliver Evans. Oliver Evans was one of the outstanding pioneers of American engineering, constructing machinery for flour mills and introducing high-pressure steam engines. In 1804 the authorities at Philadelphia commissioned him to construct a steam dredging machine which, because it could propel itself on land and in the water, Evans called the *Orukter Amphibolos*. Evans died, a disappointed man, in 1819 Before his death he destroyed a lot of drawings, and with them probably was lost the sketches of his dredger, the details of which to-day are very imperfectly known.

A Vitamin A Concentrate of High Blue Value

IN *Science* of March 16, p 255, Prof H N. Holmes, in association with H Cassidy, E Hartzler and R Manly, reports the preparation of a concentrate of vitamin A having a blue value of 144,000, that is, 14,400 times greater than the blue value of an average good medicinal cod liver oil The starting material was the non saponifiable fraction of halibut liver oil This was chilled in methyl alcohol solution, to freeze out cholesterol, etc , filtered cold under nitrogen, transferred to pentane by addition of water, dried over anhydrous sodium sulphate and then, in pentane solution, cooled to about - 70° C with the aid of carbon dioxide snow mixed with alcohol and again filtered, with careful exclusion of oxygen The cold pentane solution was next filtered through a Tswett column of very specially prepared carbon and washed completely through with pure pentane The product obtained was a pale yellow viscous oil, different preparations showed blue values ranging from 105,000 to 144,000 The authors have not yet had time to analyse their concentrate or determine its molecular weight, spectral absorption bands, extinction coefficient or biological potency Further reports of their work will be awaited with interest

Recent Acquisitions at the Natural History Museum

AMONGST recent accessions to the Zoological Department of the British Museum (Natural History) is a valuable collection of mammals, including a large series of duikers and some specimens of the giant forest hog, which has been received from Mr G Foster, assistant game warden of Uganda A small collection of important Russian mammals, which has been received in exchange from the Moscow Museum, contains specimens of *Dipus*, *Spalax*, *Citellus*, *Ochotona*, *Alactagulus*, and *Cricetulus* As a gift from the trustees of the estate of the late Mrs. Mary Joicey, the Department of Entomology has received the most valuable present of butterflies and moths to reach it since the War The collection comprises more than 300,000 specimens and includes the types of 3,000, descriptions of which were published in the main in the *Bulletin of the Hill Museum* During his life-time, the late J J Joicey probably did more to stimulate the study of butterflies and moths, especially those of Africa, than any other private individual in Great Britain The Department of Geology has received the skull of a child, about six years old, of the extinct Neanderthal race, discovered by Miss Garrod in 1926 in a cave near the Devil's Tower, Gibraltar.

IN the Department of Mineralogy 474 individual masses of meteoric iron with a total weight of 165½ lb., from the meteorite craters at Henbury, Central Australia, have been received by exchange from the Kyancutta Museum, South Australia The larger masses weigh 46½ lb , 25½ lb. and 24½ lb , the majority are small twisted pieces (meteoric shrapnel) torn from the main masses by the force of the explosions that made the craters This completes a unique display of 1,000 lb of material collected from the Henbury craters Large blocks of long-fibre satin-spar (gypsum) from East Bridgford, Nottinghamshire, have been presented by Mrs A Coville. This material is exported to the United States for the fashioning of small fancy articles, which are sold at Niagara Falls, the material being stated to come from under the Falls This export resulted from an inquiry from the United States made to the Museum about twenty years ago Mr W C Barton has presented to the Department of Botany about 8,500 sheets of flowering plants The remainder of his herbarium will be handed over shortly The present instalment includes the genus *Hieracium* and the families Ranunculaceæ to Rosaceæ with the exception of the genus *Rosa*, which was presented some years ago, and the genus *Rubus*, on which the donor is specialising in collaboration with the Rev. H J Riddelsdell The herbarium includes those of H J Riddelsdell and Mrs Foord Kelsey, the first, which is large, is particularly rich in Gloucestershire and South Wales, and the second in Berkshire, plants The first portion of the lichen herbarium of Mr D A Jones has been purchased This includes nine hundred British specimens and five hundred European Many of the British specimens are those on which records are based, and the collection supplements the very extensive Museum collections Among the purchases is a set of 149 flowering plants from Galapagos Islands collected by H J F. Schimpff

British Polar Year Expedition, 1932–33

THE Symons Lecture of the Royal Meteorological Society was given on March 21 by Mr J M Stagg, who spoke on "The British Polar Year Expedition, Fort Rae, Canada, 1932-33" The activities during the International Polar Year 1932-33 really constituted a jubilee repetition on a more extensive and intensive basis of a co-operative scheme of observational work in meteorological and allied sciences so fruitfully carried out by fifteen countries during the First Polar Year As in that year, 1882-83, part of Britain's share in the new international effort consisted in equipping and maintaining a station at Fort Rae, a trading outpost of the Hudson's Bay Company on the Great Slave Lake, north-west Canada. The programme of work of the party of six, who remained at Rae from July 1932 until September 1933, consisted primarily in obtaining as complete records as possible of the main elements in meteorology, terrestrial magnetism, aurora and atmospheric electricity, and the proximity of Fort Rae to the zone of maximum auroral frequency around the polar cap made the auroral investigations specially important. Methods of parallactic photography were employed to determine the precise position of the aurora in space The information brought back will be studied in conjunction with similar data gathered by the forty-six other co-operating countries with the view of obtaining fuller insight into the synchronous large-scale events in meteorology, magnetism and aurora, over the earth and in the atmosphere up and into the conducting layers. A large amount of material is also available for the study of the interrelationships among the varied phenomena observed and recorded during the year's activities

The New Coast-line of Antarctica

FURTHER information has come to hand concerning Consul L Christensen's discoveries in the Antarctic referred to in NATURE of March 17, p 409 Princess Astrid Land, as it was named, is now reported in the *Times* to lie in about long 86° 45′ E. and a little south of the Antarctic Circle This is to the west of and adjoining Kaiser Wilhelm Land, discovered by Dr E von Drygalski in 1902, and east of Princess Elizabeth Land, discovered by Sir Douglas Mawson in 1931 The land was sighted from an aeroplane from a distance and reported to rise for a distance of about 150 miles It is further reported that the Douglas Islands, off MacRobertson Land, do not exist Consul Christensen then took the *Thorshavn* eastward and reports that in lat. 71° 44′ S, long 134° 11′ E (? W) his seaplane could find no land to the south Proceeding via Peter Island, the ship rounded Cape Horn, discovering a new bank to the south, and made for Montevideo A number of soundings were taken in hitherto uncharted waters

Early Science in Poland

A STUDY of the development and position of science in Poland up to the end of the sixteenth century is given by Prof Kazimierz Dobrowolski in the recent issue of *Nauka Polska* (vol. 17; 1933), an annual publication devoted to the organisation and progress of science in Poland Prof Dobrowolski's account (132 pages) of Poland's contributions to early science is especially detailed for the sixteenth century itself and is well documented throughout It refers not only to the natural sciences, so far as they had then developed, but includes also incursions into theology, philosophy, logic, law and history It is evident that 'science' as understood in Poland, and in Europe generally for that matter, up to the seventeenth century was closely associated with alchemy, astrology and occult practices. But towards the close of the period under review, Prof. Dobrowolski points out that real scientific inquiries were being prosecuted in Polish centres of learning, so far as political upheavals permitted. The work of Copernicus is not only important in itself but also because it was followed by that of Francis Bacon, Galileo, Descartes and others. Early English and French contributions to scientific knowledge, for example, Roger Bacon's discoveries and writings and those attributed to Thomas Aquinas, had reached Poland and exerted some influence upon thought there The same volume of *Nauka Polska* contains some notes by Dr M. Wolfke on certain recent developments in pure and applied physics and another contributor describes life in scientific circles at Lodz.

High-Voltage Testing Equipment

ECONOMICAL considerations are leading electrical engineers to use very high voltages for transmitting electrical energy over long distances. The accessories used with high-voltage cables or overhead lines require to be specially tested This has made it necessary to build high-voltage laboratories and to design insulating devices which will withstand these high pressures. In the early days of testing, the perfection of a testing set was judged mainly by the length and appearance of the spark and the loudness of the noise it made Nowadays these measurements have to be made with high accuracy in accordance with stringent specifications On the result of the acceptance tests, errors of a few per cent may turn the scale for rejection, leading to losses of thousands of pounds to the manufacturer. In certain cases discrepancies of ten per cent are shown in the results obtained in different laboratories, leading to considerable dissatisfaction

IN a paper on high voltage testing read on December 21 to the *Institution of Electrical* Engineers by B L Goodlet, of the Metropolitan Vickers Electrical Co, Ltd, it is shown that the discrepancies are mainly due to badly designed equipment and insufficient knowledge of the performance of the testing set under various conditions They also arise sometimes from differences in the technique used in testing Single units for testing purposes are usually built for a million volts, but it is often more advantageous to utilise the well-known cascade connexion which produces the required total voltage by adding up the individual voltages of several smaller units The high voltage and low power rating of these transformers lead to difficulties in designing them The authors illustrate this by showing oscillographic records of the distorted wave forms of the current and voltage sometimes obtained In the third part of the paper a complete mathematical and experimental discussion is given of the impulse generator.

Economic Survey of 'Agriculture in the East of England

AN excellent economic survey, the second of the series, based on a sample of more than a thousand farms, has recently been published (University of Cambridge. Department of Agriculture, Farm Economics Branch. Report No 21 'An Economic *Survey of Agriculture in the Eastern Counties of* England, 1932" Pp. vi + 89. Cambridge. School of Agriculture, 1933 2*s*. 6*d* net) As a record of what is actually happening to the individual units of agriculture in the eastern counties of England, it could scarcely be bettered Reality is an excellent antidote to indiscriminate theorising in any subject; surveys such as this enable the hard facts of an industry of small units like agriculture to be ascertained Without a factual basis of this type there can be no sound future planning or adequate criticism of past planning.

THE broad facts revealed by the survey are sufficiently disquieting The depression of agriculture is common knowledge; here the extent of the depression is measured. Except for the wheat deficiency payments, the year 1932 appears to have been even worse than 1931. Of the individual farms the most profitable are the most progressive, those which aim at a high level of productivity and low labour costs per unit output; but specialisation, which would lead to the most complete mechanisation, is unsuccessful, for labour and by-products cannot be efficiently utilised The general purpose farm is the one most adapted to economical production. The whole report gives a picture of economic laws striving to operate, but without their natural consequence, the elimination of the least efficient. The moral of it all is plain: overproduction of food. Whether the English farmer should be allowed to suffer as a result of what is after all a world phenomenon is a matter of politics. What is abundantly plain is that salvation is only to a very limited extent in his own hands Mere increase in efficiency is patently not enough. In fact such increase, if world wide, will merely aggravate the disease

Recent Research in Building Practice

THE annual report of the Building Research Board for 1933 (London: H.M. Stationery Office, 2*s* 6*d*. net) contains an account of several interesting investigations. The failure of lime-plaster ceilings on lathing, whilst of frequent occurrence, is not generally due to defective materials, but to hasty work and disturbance by other types of work in the building at a time when the plaster ceilings are very sensitive to vibration. Damp walls are often caused by penetration of rain through fine cracks between the bricks and mortar. Most colourless waterproofing materials are ineffective, but an imitation stone paint showed a good resistance to weathering. Experiments on heating showed that intermittent heating from 9 30 a.m. to 5 30 p m required only three quarters of the electrical energy for continuous heating, although the latter method has been said by heating engineers to be equally economical. Testing of bricks by exposure, and of concrete piles by an ingenious piezoelectric method, are described

Science Abstracts

THE issue of the two index parts of *Science Abstracts* completes the physics and the electrical engineering volumes for 1933. More than 260 periodicals are dealt with by the editor and his 71 abstractors for physics and 57 for electrical engineering Each volume has between 30 and 40 more pages than the volume for last year. 5,491 abstracts of average length 0 247 page relate to physics and 3,078 of average length 0 257 page to electrical engineering. In each case the average length is nearly the same as last year. Reference to the abstracts is greatly facilitated by the extensive indexes provided. In the physics volume the subject index covers 208 pages and there is a key to the subject index of 15 pages and an author index of 76 pages. In the electrical engineering volume the subject index has 109 and the author index 45 pages, but there is no key. Each volume seems indispensable to the physicist or to the electrical engineer who wishes to keep himself up to date, but while every member of the Physical Society and possibly of the American Physical Society gets a copy of the physics volumes the Council of the Institution of Electrical Engineer, reported in May last that only 9 per cent of its members subscribed for copies of the electrical engineering volume.

German Association of Men of Science and Physicians

THE German Association of Men of Science and Physicians (Gesellschaft Deutscher Naturforscher und Ärzte) is modifying its policy with the view of overcoming excessive specialisation. It is proposed to emphasise the tasks and problems common to many or all branches of science and medicine, and to promote discussion on these common topics on the widest possible basis. The annual meeting of the Association will last not more than three and a half days. The Council of the Association will only arrange the general sessions, the main group and joint sessions, and popular evening lectures The general sessions will be devoted to topics in which some definite results have been reached or to problems of immediate importance. If discussion does not follow these addresses by selected speakers, the same theme may be handled more freely in joint sessions of sections. The Council will abandon the attempt to arrange meetings of the separate sections, leaving them to deal individually with the local committee. It has been the custom for some years past that allied and associated societies should meet at the same place, and either before or after the formal meetings of the Association This custom is to be continued at the next meeting in Hanover (Sept 16–20, 1934), and with the help of the local committee. An innovation is the *Zweckverband* of German scientific and medical congresses, the aim of which is to maintain contact between these congresses so that whilst specialisation goes forward they shall not be shut off from each other The purpose of this union is to publish the dates, places and programmes of these congresses; for example, various medical congresses take place in April and May next

Royal Geographical Society's Awards

HIS MAJESTY THE KING has approved the award of the Royal medals as follows *Founder's medal* to Mr Hugh Ruttledge, for his journeys in the Kumaon and Garwhal Himalaya extending over eight years and his leadership of the Mount Everest Expedition, 1933; *Patron's medal* to Capt. Ejnar Mikkelsen, for his explorations in the Arctic between 1900 and 1912 and for his work in Eskimo re-settlement on the east coast of Greenland The Council has made the following awards: *Victoria medal* to Mr. Edward Heawood, for his work on the history of geography and cartography and his devoted service to the Society as its librarian; *Murchison grant* to Mr. John Rymill, for his work in Greenland and leadership of the party after the death of Mr. H. G. Watkins on his second expedition; *Back grant* to Dr. D. N.

Wadia, for his studies of the Himalayan axis and other problems of Indian geomorphology of importance to geographers; *Cuthbert Peek grant* to Mr Edward Shackleton, to assist him in his proposed expedition to Ellesmere Land, *Gill memorial* to Mr W B. K. Shaw, for his explorations and studies in the Libyan desert

The Night Sky in April

JUPITER is now exceedingly well placed for observation, as it is in opposition on April 8 It is a very conspicuous object in the sky, rising a little after sunset The bands and satellites make this planet a very interesting telescopic object. The planetary nebula, N.G.C. 3242, R A 10h 21m, Dec 18° 15′ S, a little south of μ Hydræ, is now conveniently placed for observation It is of slightly elliptical shape and bears magnifying well There are two clusters visible to the naked eye which repay examination with a small telescope. These are N G C. 2632 at 8h 35m. and 20° 15′ N (Præsepe), and N.G C 2168 at 6h 4m. and 24° 20′ N The last mentioned is in Gemini, and now appears in the western sky in the early evening

Announcements

THE Chemical Society will celebrate the centenary of the birth of Mendeléeff in 1834 by a meeting, on April 19 at 8 p m., to be held in the lecture theatre of the Royal Institution, when Lord Rutherford will deliver a lecture entitled "The Periodic Law of Mendeléeff and its Interpretation" The lecture is open to fellows of the Chemical Society and their guests.

PROF J C MCLENNAN will deliver the twenty-fifth Kelvin lecture before the Institution of Electrical Engineers on April 26, taking as his subject "Electrical Phenomena at Extremely Low Temperatures"

PROF JOHAN HJORT will deliver the Huxley Memorial lecture of the Imperial College of Science at the Huxley Building, Exhibition Road, South Kensington, S.W.7, on May 4, at 5 30. The subject of the lecture will be "The Restrictive Law of Population". Prof Hjort is professor of marine biology in the University of Oslo, and is well known for his work on the development of the fishing industry and oceanographical research in North European, Atlantic and Canadian waters. He was elected a foreign member of the Royal Society in 1916.

SOME details were given in NATURE, of March 17, p. 412, of the mirror which is to be made for the new 200-in telescope for the California Institute of Technology. According to the New York correspondent of the *Times*, the glass was poured on March 25, an operation which took ten hours to complete, ten months are to be allowed for the twenty tons of glass used to cool

MR. EDWIN THOMPSON, of Liverpool, has been selected by the Council of the Society of Chemical Industry as president for the year 1934–35. He will take office at the annual meeting of the Society which is to be held in Cardiff on July 16–20. Mr. Thompson is governing director of Messrs. Thompson Capper Wholesale, Ltd., manufacturing chemists of Liverpool, and has for many years been associated with the work of the Society He is on the General Committee of the British Association, and at the Liverpool meeting in 1923 he did valuable work as honorary secretary He was president of the British Waterworks Committee when in 1930 it held its annual meeting in Liverpool Mr Thompson originated the idea which eventually led to the formation of the Lancashire Industrial Development Council

AT the first scientific meeting of the Microchemical Club held at the Lister Institute on March 17 the following officers were elected for the year 1934–35: *Chairman*, Dr Janet Matthews (Imperial College of Science); *Hon Treasurer and Librarian*, Dr L H. N Cooper (Marine Biological Laboratory, Plymouth), *Honorary Secretary*, Dr S J. Folley (National Institute for Research in Dairying, Shinfield, near Reading)

THE Ministry of Agriculture and Fisheries has recently issued two new Advisory Leaflets, "Turnips, Swedes and Kohl-Rabi" (No 189) and "Bracken" (No 190) The former discusses the soils and climate most suitable for the growth of the three root crops mentioned, their varieties and cultural treatment. Many useful practices are described, and the subject matter is quite up-to-date The leaflet on bracken shows that this plant has a few slight uses—as bedding and food for pigs—but causes damage far beyond its benefits. The chief methods of eradication are cutting off the shoots in June for two or three years in succession, and the application of lime and phosphate It is suggested that dragging a chain harrow over the newly-emerged sprouts in early spring is also a good method of control

MESSRS. DULAU AND COMPANY, LTD, of 32 Old Bond Street, London, W 1, have recently published Catalogue No 218, containing an extensive list of books on botany and gardening, which they have for sale. More than eight hundred volumes, mainly of historical interest, are enumerated, and a further extensive list of standard modern works on gardening is given Such outstanding contributions to botanical science as Nehemiah Grew's "Anatomy of Plants", several writings of Linnæus and a few early "Herbals" are combined with more modern writings

APPLICATIONS are invited for the following appointments, on or before the dates mentioned.—A mechanical engineer at the Royal Arsenal, Woolwich—The Under-Secretary of State (M G O 4), The War Office, London, S W.1 (April 7). A head of the Physics Department, a lecturer in electrical engineering, and a teacher of geometrical drawing and elementary mathematics at the Wigan and District Mining and Technical College—The Principal (April 9) A lecturer in geography at the Homerton Training College for Women, Cambridge—The Principal (April 23) A lecturer in chemistry at the University of Reading—The Registrar (May 7). A resident woman tutor in mathematics at the Edge Hill Training College, Ormskirk—The Principal.

Œstrogenic Hormone in the Urine of the Stallion

IN further investigations on the œstrogenic hormone, which to a large extent is excreted in the urine of the stallion[1], we have examined the influence of this hormone on the secondary sexual characteristics, especially on the mammary gland By the use of follicular hormone, Laqueur was able to induce lactation of male guinea pigs We have now observed the same effect with the hormone obtained from the urine of the stallion and in the actual cases the lactation of the male animals has continued for 21 days

Another typical effect of the follicular hormone, the hyperpigmentation of the mamillæ and the areolæ of the nipples (Bloch and Schrafl), is also exhibited after the injection of the œstrogenic hormone of the urine of the stallion These investigations show that all the *biological reactions which are characteristic of the follicular hormone are exhibited by the œstrogenic hormone of the urine of the stallion*

How can the occurrence of so great a quantity of œstrogenic hormone in a male organism be explained ? I believe that the female hormone which is regularly present in the male organism represents a normal physiological product of the metabolism of the sex hormones, especially since—due to our present chemical knowledge (Butenandt, Marrian, Doisy)—a conversion of the male hormone into the female one appears to be quite possible. I am further of the following opinion · the metabolism of the sex hormones is, in the main, the same in both sexes. At first, the male sex hormone is synthesised from substances which are still unknown, and the male hormone is then converted into the female one The specific sexual characterisation is solely due to a quantitative regulation of this general process of metabolism In my opinion, the observations with male equines support this hypothesis from the biological point of view From the fact that production of the female hormone in large quantities in the stallion occurs only during sexual maturity—when the male hormone is produced—it follows that there exists a connexion between the male and the female hormone It is possible that in the testes of the stallion—as compared with other organisms—a very great production of male hormone occurs, and that this surplus of male hormone is immediately destroyed by converting it into female hormone and then rapidly excreting the latter It is impossible to say why this hyperproduction is characteristic of equines The fact that a not inconsiderable amount of male hormone is to be found in female animals, including women (Loewe, Tschernung), is also in harmony with this hypothesis.

The male hormone represents an intermediate product in the formation of the female one. The regular occurrence of female hormone in the male organism is explained as due to the conversion of part of the male hormone into the female one. In the female organism the male hormone is supposed to constitute a previous product of the female hormone and in the male organism the female hormone is supposed to constitute a degradation product of the male hormone. The dehydrogenation products which Girard has isolated from the urine of pregnant mares (equilin, hippulin and equilenin) do accordingly constitute the final products (which at the present time are known) of the degradation series of the male hormone

Metabolism of sex hormones outside the sexual glands (extragonadial metabolism) can also occur and this has been the object of a joint communication of H. v Euler and myself[2]

A Rapid Test for the Diagnosis of Pregnancy

CURRENT biological tests for the diagnosis of pregnancy or detection of ovary-stimulating substances in gland extracts and body fluids have the main disadvantage that several days must elapse before a result can be obtained Attempts have been made to remedy this by making use of the doe rabbit, because in this animal a response (ovulation) can be obtained in less than 14 hours[1]. The rabbit, however, requires a good deal of care in order to obtain consistent results. It is essential to know the previous history of does employed, and preferably only to use them a short time after parturition. Even so, variation in response to injection may be so great as to necessitate the use of more than one doe in order to be sure of the result

The test described in the present note depends upon the observation by Hogben[2] that extraneous ovulation in the South African clawed toad (*Xenopus Lævis*) can be induced by injection of extracts of the anterior lobe of pituitary. *Xenopus* can be obtained easily and cheaply in large numbers Several hundreds can be kept without difficulty at the sole cost of a few handfuls of raw meat once a week, provided that they are kept in a warm well-lit room and that their water is changed after feeding Ovulation does not occur spontaneously in captivity Ova shed as a result of injection are clearly visible and extruded in large numbers. No doubt exists, therefore, as to the validity of a response

During the past two years, work has been carried out on the use of *Xenopus* for detecting and estimating ovary-stimulating substances in tissue extracts and body fluids such as pregnancy urine The following main points have emerged[3]

(*a*) At a temperature of 20°–25° a single injection of an active preparation into the lymph sac is followed in the great majority of cases by complete ovulation within 9 hours. Very often a response is obtained in less than 6 hours.

(*b*) A given batch of toads can be used repeatedly, provided that a rest of at least one week is allowed to elapse between successive injections

(*c*) A definite quantitative relationship holds between dosage and response.

As a result of the first observation, a test for early pregnancy has been elaborated, the exact procedure of which depends upon the time which has elapsed from the last missed menstrual period :—

(1) If one month or more has elapsed, untreated urine from the suspected case is used. Ten toads

are injected in the lymph sac with 1 ml. A positive diagnosis is made if ovulation occurs in at least 5 out of 10 animals within 9 hours. The correct temperature is obtained by keeping vessels containing the toads in a room heated to 20°–25° by means of an electric fire.

(2) If less than one month has elapsed, a sample of 100 ml of urine is precipitated with acetone and centrifuged The residue is suspended in 10 ml. of distilled water and 1 ml of the suspension injected into each of 10 toads A positive result is indicated as before This procedure is necessary owing to the facts that in very early pregnancy there is an insufficient amount of ovary-stimulating substance in 1 ml. of urine to produce a response, and that a volume of fluid greater than 2 ml cannot be injected into the lymph sac without risk of non-absorption

A full account of this work will appear later So far no incorrect diagnosis has been made In view of the quantitative nature of the test, it is hoped to distinguish normal early pregnancy from ectopic pregnancy or conditions such as hydatidiform mole

Uniformity in Bibliographic Particulars

THE excellent letter from the librarian of the John Innes Horticultural Institution, published in NATURE of March 10 (p 380), is welcome to the Committee on Zoological Bibliography and Publication appointed by the British Association in 1895 and still working. Most of Miss Schafer's recommendations have from time to time been made by this Committee in its published reports as well as in its considerable correspondence. May I dot the i's of one or two ?

In the order of citation the date should occupy a more prominent position in making references my Committee would place it immediately after the author's name, in catalogue slips it is usual to place it at the end In any case the month, and even the day when known, should precede the year.

The practices to which Miss Schafer rightly objects are sins of omission ; but there are sins of commission Details given by a publisher, or appearing on the printed cover, should never be taken at their face value, until one has learned by experience that the particular publisher or editor is to be trusted, and even of them the most accurate can make mistakes. The printed date, as Miss Schafer has noted, is frequently wrong ; I have catalogued one paper that had four dates—all incorrect. When priority is in question a printed date inclines to be earlier than the correct one ; but textbooks tend to bear a date later than the actual publication. The title on the wrapper is often inexact and sometimes absurd ; it is made up by the printers. The use of the term 'plate' is frequently incorrect. A plate, properly speaking, is an addition or insertion and not part of the printed sheet ; the fact that an illustration occupies a whole page does not make it a plate, neither should an inserted plate bear a page-number. But the issue of plates without any numbers at all is probably more exasperating, only outdone by the numbering of some and not of others.

For the worker, as distinct from the cataloguer, it is a convenience to have on every page-opening the name of the journal, the volume number, and the date, as well as the running title of the article But even the cataloguer benefits by this when separates have been formed by the breaking up of a volume

Printers have a habit, not only of re-paging, but also of rehandling the type so that a paragraph originally on, say, p 15 is shifted to p 14 They may even change the numbering of the text-figures. Printers cannot be expected to know better ; authors rarely have a say in the matter, therefore my Committee has always appealed to the editors. Editors unfortunately are not permanent, so that one has to be constantly repeating one's protest. It is comforting to find that one is not alone

Just one point in Miss Schafer's letter leaves me uncertain Why does she call roman numerals "eye-straining" ? I will grant that the present generation does not seem educated up to them, but they have their advantages. Instead of printing 'Series 3, vol. 12, pages 31–43, plates 7–10', it is convenient to print or write '(3) XII, 31–43, vii–x' The modern use of clarendon arabics for the volume number may be an improvement, but it involves intermittent recourse to a different fount by the compositor, which must be rather worrying to him

Diplogen and Fish

IN recent months we have been carrying out experiments on the behaviour of fish in heavy water We find that goldfish (*Carassius auratus*) behaved quite normally in the heavy water in which they were kept As heavy water was to be used as indicator of normal water, we had to carry out our experiments in water containing only 0 5 mol. per cent of diplogen, and it is therefore still possible that a higher concentration of this isotope in water exerts effects upon fish

The aim of our experiments was to follow the exchange of water between the fish and their surroundings, using heavy water as an indicator of the movement of the total water The use of radioactive isotopes for such purposes is well known While the latter are practically chemically identical, and as such are entirely trustworthy indicators, that is not the case with the isotopes of hydrogen Heavy water is, therefore, only to be used with great caution as an indicator of ordinary water However, when using very dilute solutions of heavy water, we may expect that the rate of exchange of heavy water molecules between the fish and its surroundings will not be very different from that of the normal water molecules. By measuring the speed at which the heavy water enters the body of the fish we can therefore conclude at what rate approximately the exchange of water between the fish and its surroundings takes place.

Some twenty fish having a total volume of about 10 c.c were kept in about 60 c c. of water containing 0 5 mol. per cent diplogen water. After a certain time the fish were removed and the decrease of the density of the surrounding water was determined. The fish were then placed in normal water, and the rise in the density of the latter due to the entrance of heavy water molecules leaving the body of the fish was determined The results are as shown in the accompanying tables.

TABLE 1

Rate of entrance of heavy water into fish

	Time in hours	Decrease of the heavy water content of the surrounding water	Decrease expected in the case of equal distribution of the heavy water between fish and surrounding water
I	1	32 p c	30 p.c
II	4	32 p c	29 p.c
III	15	33 p c	30 p c

TABLE 2

Rate of loss of heavy water by the fish

	Time in hours	Initial heavy water content of the fish	Decrease of the heavy water content of the fish after the experiment	Decrease expected in the case of equal distribution of heavy water between fish and surrounding normal water
I	1	0 27 p c	68 p c	51 p c
II	4	0 27 p c	68 p c	67 p c
III	10	0 26 p c	86 p c	86 p c

It follows from the above that, at least in a small fish, within a few hours nearly all the water molecules leave the body of the fish, making way for water molecules derived from the surrounding water. It should be borne in mind that most fish contain about 80 per cent water.

Band Spectrum of Aluminium Deutride

BEING in possession of heavy water obtained by the electrolysis of some hundreds of litres of water, kindly furnished us from Norduska Syrgasverken in Örebro, we have started investigations on the isotope effects in the band spectra of hydrides The following preliminary results are given for the spectra of AlH and AlD; the former spectrum is reanalysed in order to get more exact data for comparison.

Table 1 gives the origin of the bands in $^1\Pi \rightarrow {}^1\Sigma$ from measurements in the second order of a 21-ft. concave grating (dispersion 1A /mm) The bands of the new AlD molecule are indicated by asterisks.

Table 1

v'' \ v'	0	1	2
0	23470 91 23536 79*	24554 29 24379 89*	
1	21845 73 22354 75*	22929 11 23197 85*	—— 23868 54*
2		21359·81 22045 29*	—— 22715 96*
3		19844·94 20921·67*	

We have applied the theory on isotope effects in band spectra to the normal state $^1\Sigma$ as being most favourable on account of its regular structure. The harmonic frequencies ω_e of the nuclear vibrations and their anharmonic corrections are given below:

AlH		AlD	
ω_e	= 1682 45 cm $^{-1}$	ω_e^i	= 1212·04 cm.$^{-1}$
$\chi_e\omega_e$	= −29 089 ,,	$\chi_e^i\omega_e^i$	= −15 145 ,,
$y_e\omega_e$	= 0 242 ,,	$y_e^i\omega_e^i$	= 0 090 ,,

Our third order polynom, representing the vibrational levels in $^1\Sigma$, does not converge at high v numbers and must therefore be completed by terms of higher order to fit into the known value of dissociation (D = 3 1 volts). The small corrections to be applied on the frequencies given above are, however, of minor importance in this connexion

From analysis of the band structure we have calculated the coefficients of rotation in $^1\Sigma$ up to the sixth order in $(k+\frac{1}{2})$ as follows:

AlH		AlD	
B_e	= 6 3955 ± 0 0003	B_e^i	= 3 3190 ± 0 0003
α_e	= 0 1850	α_e^i	= 0 0689
D_e	= −3 8 × 10^{-4}	D_e^i	= −0 98 × 10^{-4}
F_e	= 3 × 10^{-7}	F_e^i	= 0·05 × 10^{-7}

These data applied to the general problems on isotopes are of interest as will be discussed below to some extent. Primarily, we assume that the mass-spectroscopic value based on the atomic weight of the heavy isotope of hydrogen 2 0136, obtained by Bainbridge[1] is correct. If this is true, ρ^2 = 0 51838 corresponds to the ratio of the reduced masses of the isotopic molecules as deduced from the atomic weights 1 00778 and 26 97 of hydrogen and aluminium respectively. Errors in the latter value amounting to 3 parts in 1000 will be of no influence on the value of ρ^2 given above. Now generally,

$$\frac{\omega_e^i}{\omega_e} = \rho \left(\frac{\varkappa^i}{\varkappa}\right)^{\frac{1}{2}}$$

where $\varkappa^i$ and $\varkappa$ are the forces of direction in the case of harmonic vibrations. As these forces are to be derived from the interaction between the charged particles in the molecule, the isotope principle requires their ratio to approach unity to a very high degree of exactness However, inserting our values for ω_e^i and ω_e ($\rho^2 = 0{\cdot}51898$), we find $\frac{\varkappa^i}{\varkappa}$ = 1 00057, corresponding to an increase in the binding forces of the nuclei at their position of equilibrium in AlD as compared to the ordinary AlH.

A similar effect appears in the values of the nuclear separations, as shown by finding the ratio of the moment of inertia ($B_e^i/B_e = \rho^2$) in both molecules. With the same assumptions as before, we get ρ^2 = 0 51896, corresponding to an approach of the nuclei in AlD amounting to 0·056 per cent, which means a small displacement of 9×10^{-12} cm.

On the other hand, rejecting the mass-spectroscopic value of ρ^2, our results point at an atomic weight for deuterium of 2·0113, far less than that found by Bainbridge At present, however, we postpone the discussion of the causes of these divergencies, awaiting the results of investigations of the band spectra of other deutrides (BiD, HgD, etc.) now in progress in this laboratory.

Details regarding the structure of the activated $^1\Pi$ state in AlD will be given later, after we have investigated the remarkable pressure effect which governs this rather unstable state. Incidentally, it may be mentioned that the measured Λ-doubling agrees with the formula: $T_d - T_c = q\, k(k+1)$, where q_{AlH} = 0·009 cm^{-1} and q_{AlD} = 0 00225 cm.$^{-1}$.

Crystal Structure of 1, 3, 5-Triphenylbenzene

IN a recent communication on the crystal structure of 1, 3, 5-triphenylbenzene, Dr. Kathleen Lonsdale[1] discusses the results of recent X-ray measurements on the crystal and concludes that the planes of the benzene rings of the molecules cannot coincide with the (001) plane of the crystal, as has been suggested by earlier investigators, but must be inclined to this plane.

This conclusion is fully supported by the results of our magnetic measurements on this crystal, and the magnetic data further enable us to calculate approximately the inclinations of the benzene rings to the (001) plane. The crystal is orthorhombic and its principal gram molecular susceptibilities along a, b and c axes are

$$\chi_a = -141\,;\ \chi_b = -155;\ \chi_c = -309$$

respectively, in 10^{-6} C.G.S. E.M.U.

The c axis is thus an axis of approximate magnetic symmetry, the susceptibility along this axis being numerically greater than that along perpendicular directions by 161×10^{-6} per gram molecule. Had the planes of all the benzene rings in the unit cell been coincident with the (001) plane, the difference between the susceptibilities along the c axis and along perpendicular directions would have been much higher, namely, 216×10^{-6} per gram molecule. This shows that the benzene rings are inclined to the (001) plane, the angle of inclination θ being given by the relation $\cos^2\theta - \frac{1}{2}\sin^2\theta = \frac{161}{216}$; that is, $\theta = 24°$

The optical constants of the crystal also support the above orientation of the benzene rings The gram molecular refractivities (defined as usual by $R = \frac{n^2-1}{n^2+2}\cdot\frac{M}{\rho}$) of the crystal for vibrations along the a, b and c axes are[2]:

$$R_a = 115{\cdot}5\,;\ R_b = 115{\cdot}0\,;\ R_c = 77{\cdot}6$$

respectively, for the D lines. R_a and R_b are thus nearly equal and much greater than R_c, as we should expect If we assume all the benzene rings to lie in the (001) plane, and *neglect the mutual influence of the optical dipoles induced in the different benzene rings*, we obtain for the birefringence of the crystal

$$R_a - R_c = R_b - R_c = 65$$

The much smaller birefringence actually observed for the crystal, namely, $R_a - R_c = R_b - R_c = 38$, points to an inclination of the benzene rings to the (001) plane, at an angle θ determined, as in the magnetic case, by the equation

$$\cos^2\theta - \tfrac{1}{2}\sin^2\theta = \tfrac{38}{65}, \text{ or } \theta = 32°.$$

Since the mutual influence of the dipoles is by no means negligible as we have assumed in the calculation, this value of θ must be taken to represent only the *order of magnitude*, and is therefore not inconsistent with $\theta = 24°$ obtained from the magnetic data.

Production of Heat in Supraconductors by Alternating Currents

IT has frequently been suggested[1] that supraconductivity is a phenomenon not due to the normal electrons which cause ordinary electrical conductivity, but that one may have to take into account supraconducting electrons as opposed to the ordinary electrons Such a hypothesis would seem to be in accord with the observed fact that there is no discontinuity in the heat-conductivity at the transition point[2]. In this case the following method would seem to enable one to determine the number of supraconducting electrons.

If the electrons taking part in the ordinary conduction above the transition point preserve their properties below it, their damping, characterised by the specific electrical conductivity σ, would presumably not vary appreciably. This cannot be observed with direct current, since the supraconducting electrons prevent one applying the electrical field. With an alternating current of sufficiently high frequency, however, this screening effect is not complete on account of the inertia of the electrons; one might therefore expect an alternating current to produce motion of the normal conducting electrons with a consequent production of heat. By measuring this heat, it should therefore be possible to demonstrate the existence of these normal electrons and prove whether their general properties change at the transition point

For ordinary electrons the relation between the current density $\mathbf{J}$ and the strength of electric field $\mathbf{E}$ is:

$$\mathbf{J} = \sigma\mathbf{E}$$

If we take into account the existence of the supraconducting electrons, we must because of their inertia replace this equation by

$$\mathbf{J} = \frac{1}{\Lambda}\mathbf{E} + \sigma\mathbf{E} \qquad (1)$$

where the inertia term

$$\Lambda = m/ne^2 \qquad (2)$$

depends, apart from universal constants, only upon the number n of electrons per cubic centimetre

If we calculate the distribution of an alternating current in a supraconductor according to formula (1), we find that the current flows near the surface in a layer of finite thickness d. Considering in the first place not too high frequencies ν, such that $\sigma\Lambda\nu \ll 1$, and neglecting terms of second and higher powers in $\sigma\Lambda\nu$ (and the influence of the displacement current) we find

$$d = \sqrt{\Lambda c^2/4\pi} \qquad (3)$$

In this approximation the thickness is therefore independent of the second term in (1), that is, the term taking account of the normal electrons, and is also independent of the frequency[3].

This term is important, however, for the production of heat. While with direct current only the magnetic field $\mathbf{H}$ occurs in the layer, with alternating current an electric field $\mathbf{E}$ appears which is given by Maxwell's equation curl $\mathbf{E} = -\frac{\mu}{c}\mathbf{H}$. It is this which gives rise to the heat.

The amount of heat Q produced per unit volume in unit time (neglecting higher powers of $\sigma\Lambda\nu$) amounts to:

$$Q = (2\pi\nu)^2\sigma\Lambda^2\,\overline{J^2} \tag{4}$$

where $\overline{J^2}$ represents the mean value of J^2 averaged over the time By means of this equation we can therefore determine either the number n of supraconducting electrons (by (2)) or the thickness d of the layer in which the current flows (by (3)). In this effect, in contrast to others, the proportionality with ν^2 is characteristic. Thus a production of heat which might occur each time the supraconducting current was switched on would, of course, be proportional to ν only

For high frequencies, for example infra-red radiation, in which the value $\sigma\Lambda\nu$ is no longer small compared with 1, the inertia of the normal conducting electrons must be taken into account For at low temperatures the value of the normal conductivity is very large and therefore the inertia term is much more important than it is at room temperature In this case it is therefore necessary to distinguish between Λ_s and Λ_n, corresponding to the supraconducting and normal electrons, and formula (1) must be replaced by

$$\mathbf{J} + \sigma\Lambda_n\,\mathbf{J} = \frac{1}{\Lambda_s}\,\mathbf{E} + \sigma\,\mathbf{E}\left(1+\frac{\Lambda_s}{\Lambda_n}\right) \tag{5}$$

If the number of supraconducting electrons is small compared with the number of normal electrons ($\Lambda_s \gg \Lambda_n$), their influence at these frequencies will be so small that the absorption of infra-red radiation should be nearly the same both above and below the transition point

Though the conditions we have considered have been idealised considerably, yet it stands to reason that the supraconducting currents are not surface currents in the mathematical sense Once one admits any finite thickness for the layer in which the current flows (even though it be represented by a formula different from (2)), there must always be in the case of alternating current an inner electric field If therefore normal conduction electrons exist, we must expect a production of heat characteristic of each supraconductor

Experiments to measure this production of heat with the view of determining whether such normal electrons exist and, if a positive result were obtained, to make deduction of the number n of supraconducting electrons, or at any rate the thickness d of the layer, were carried out in Prof Simon's laboratory in Breslau in 1933[4] As they were prematurely interrupted, definite results are not yet available. They are being continued and it is hoped to report upon them in due course

[2] W J de Haas and H Bremmer, Comm Leiden, No. 214 *d*, 1931.

[3] This thickness is, of course, the same as that which has been calculated independently for direct current by R Becker, G Heller, F Sauter, *Z Phys*, 86, 772, 1933 These authors, however, do not take into account the possible existence of normal electrons, which are of no interest for direct current problems but would be fundamental if they exist for the effect we are considering here (Added in proof) Therefore W Braunbeck in a recently published paper (*Z Phys*, 87, 470, 1934) obtains no production of heat calculating the propagation of electric waves through a supraconductor without considering the existence of normal electrons

Vitamin B_2 and the Pellagra-like Dermatitis in Rats

IN our first experiments on the concentration and isolation[1] of vitamin B_2, we failed to observe definite changes in the skin and fur, such as those described by J Goldberger and R D Lillie[2], and by H. Chick and M. H. Roscoe[3] and several other authors, in rats fed on diets containing the antineuritic vitamin in a purified form (for example, alcoholic extracts of wheat or maize, Peters's antineuritic concentrate from yeast, crystalline vitamin B_1 preparations). The flavin pigment was identified by us with vitamin B_2 by its growth-promoting properties. It was therefore a question for further investigation whether in these circumstances it was also identical with the 'anti-dermatitis factor' and in particular with the 'pellagra preventing factor'

The chief and obvious reason for designating as pellagra-like this peculiar condition produced in rats receiving the antineuritic vitamin as their sole source of 'vitamin B' is the general symmetric dermatitis. *This occurs especially on the backs of the forepaws, forearms and backs of the hind paws, the medial surface of the fore and hind legs, and the ears* It has also been the basis for its supposed identification with human pellagra (which has not been sufficiently corroborated clinically) In addition to this pellagrous condition, several authors take account of other less special symptoms soreness of the mouth, nose, and spectacle-like rings of inflammation around the eyes, a tendency for lids of one or both eyes to adhere together, with an accumulation of dried secretion on the margin of the lids, in some instances loss of fur, particularly on the neck, shoulders or back (saddle-like areas of baldness), small, dry, cream coloured scales or yellowish crusts over a large part of the body Occasionally these less specific symptoms may prevail and give quite a different aspect to the pathological appearance

The view has already been considered by J Goldberger that these two classes of dissimilar skin changes are to be ascribed to a deficiency not only of vitamin B_2 but also of another component of the vitamin B complex Hitherto no definite proof of this has been given.

In recent investigations, we have been able to fill this gap The result was an unexpected one We fed rats with an ordinary vitamin B-free diet (caseinogen A B. Glaxo 18 per cent, rice starch 68 per cent, butter fat 9 per cent, cod liver oil 1 per cent, salt mixture 4 per cent) supplemented by a vitamin B_1 preparation from yeast highly purified by the method of Windaus *et al.* (1 pigeon-unit = 8–12 γ) and with vitamin B_2 (lactoflavin 10 γ daily). In a large number of the animals we observed pellagra-like changes in the skin In order to avoid symptoms of B_4 deficiency (loss of co-ordination, ataxia, spastic gait) it appeared necessary to give a higher dose of the vitamin B_1 preparation. The appearance of pellagra-like symptoms was accelerated by the administration of 4–6 pigeon units, whereas when smaller doses were given the skin symptoms were not observed at all or else only in a very moderate degree[4]. When the B_2-free diet of A. Bourquin and H. C. Sherman[5] was used, the addition of B_1 and B_2 supplements produced pellagra-like skin changes The classical picture of the symmetrical pellagra-like dermatitis, with reddening and swelling of the fore and hind paws and ears as the specific characteristics of the condition, occurred particularly distinctly when egg-white (3–5 c.c. daily) was added to a vitamin B-free diet supplemented by vitamin B_1, or to the Bourquin-Sherman diet Administration of vitamin B_2 (lactoflavin) intensified the symptoms even more, and here it should be mentioned that egg-white is already known to be rich in vitamin B_2 (H. Chick and M. H Roscoe[6])

These effects were obtained with remarkable regularity and we must conclude from the results that the 'pellagra-like' dermatitis is not produced by a lack of vitamin B_2, as it is isolated in flavin pigment We are much more readily able to produce the pellagra-like dermatitis, unaccompanied by non-specific and uncharacteristic secondary symptoms, in the presence of B_1 (perhaps contaminated with B_4) and B_2. This pellagra-like dermatitis can be cured by the administration of the B_1+B_4 eluate from the charcoal adsorbate from yeast extract as prepared by the method of Kinnersley, O'Brien, Peters and Reader[7] This antidermatitis factor cannot be identical with B_4 for the following reasons (1) our animals show no signs of B_4 deficiency, (2) the skin lesions can be alleviated by alkaline autoclaved marmite, in which according to Reader the vitamin B_4 must have been destroyed One might rather identify it with the alkali stable factor *Y* of H Chick and A M Copping or the B_5 pigeon factor In order to avoid confusion, we have for the time being named this 'rat pellagra preventive factor' in its narrow sense vitamin B_6

By the administration of B_1+B_4 $(+B_6)$ or Peters's yeast eluate for 10–15 weeks, skin changes were certainly produced, but they were never pellagra-like, but 'unspecific' as above mentioned and mostly only trivial These skin changes can be cured by B_2 In this sense, B_2 is also a skin factor and it can be understood that egg-white, for example, which contains no B_6, can cure these 'non-specific' skin changes because it is rich in B_2 (cf Chick and Copping)

So we have been able to separate vitamin B_2, the antidermatitis factor, into two components—the real vitamin B_2 (flavin) and vitamin B_6 *

Effect of Mitogenetic Rays on Eggs of *Drosophila melanogaster*

THE different methods for the demonstration of Gurwitsch rays have in common that the technique is always subtle and requires much practice; Magrou alone has described a simple method while using the eggs of the sea-urchin, but these eggs are only obtainable in certain months of the year and in marine laboratories; so we have sought for a more convenient object and have found it in the eggs of *Drosophila melanogaster*.

We used strips of paper, with a layer of agar and ordinary treacle; after deposition of the eggs by the flies, we put the paper strips into Petri dishes and moistened them with water The source of our Gurwitsch rays was a culture three hours old of *Staphylococcus pyogenes aureus* in ordinary broth. The broth was put into test-tubes of fused silica closed by corks, and placed on the opened Petri dishes containing the paper strips with the eggs. The most suitable time for irradiation was found to be 20 minutes Afterwards the two Petri dishes (irradiated and control) were closed with their covers of glass, and kept under the same conditions. We counted the larvæ that were hatched each day and sometimes every couple of hours; so we could always choose an epoch, when only 20–60 per cent of the control eggs were hatched, while a much greater number of the irradiated eggs were hatched

The following results, which speak for themselves, were obtained from nine experiments

Controls			Irradiated Eggs				
No of eggs	No hatched	Per cent hatched	No of eggs	No hatched	Per cent hatched	Time of irradiation	Diff (per cent)
39	25	64	51	45	88	15–20 min	24 ± 10 6

The Pectoral Fin of *Coelacanthus tingleyensis*

THE structure of the internal skeleton of *Coelacanthus tingleyensis*, Davis, was first described[1] and figured[2] by Wellburn as having six basal supports radiating out from the shoulder girdle in a manner similar to those in a pectoral fin described by Woodward[3] from the Talbragar Beds In view of the recent work of Stensiö[4] on the structure of this fin in the Triassic Coelacanth *Laugia groenlandica*, we have re-examined Wellburn's specimen, which is now in the Leeds City Museum (No D17), and found that the fin does not show the radials described by Wellburn. This we consider is important and worth putting on record, for it would have been difficult to reconcile the actinopterygian-like arrangement described by Wellburn with the archipterygial type of fin present in the later Triassic Coelacanths.

Research Items

Archæology of Hawaii. A survey of the archæology of Oahu based on field work in 1930 by Mr. J. Gilbert McAllister (*Bull.* 104, Bernice P. Bishop Museum, Honolulu) has been undertaken in order to place on record such evidence as remains of the people who were in Hawaii when it was first visited by European voyagers European culture and exotic vegetation introduced into the island are rapidly destroying the sites; but knowledge of them is still treasured by the older inhabitants Various types of remains are here recorded. The old Hawaiian places of worship fall into two groups, large communal places of worship, for which the term *heiau* is generally employed, and small shrines at which offerings were made The former are the most interesting remains now found on Oahu Of these there are 27, while on 19 other sites portions remain. In size they range from 50 ft × 40 ft. up to 570 ft × 170 ft. They may be classified into walled structures, terraced structures and walled and terraced structures. The sacrificial *heiau* was the highest type On it human sacrifices were offered, and it could be built only by a king It was essentially a war temple. The husbandry *heiau* was used chiefly to ensure the prosperity of the people. With few exceptions the *heiau* were built of natural basalt The smaller places of worship were fishing shrines, family shrines and road shrines, those functioning in connexion with fishing rites being by far the most important of these. The ceremony consisted in making an offering It was made by one individual who was regarded as the guardian of the shrine Several were sacred to certain fish only. Four shrines consisting of small enclosures were noted, but probably most shrines consisted of single stones The family shrine was an integral part of every household; while the road shrine was a place where offerings were made to some spirit

Ostracod Feeding Mechanisms. Prof H. G. Cannon has already given us valuable information on the feeding mechanism of various Crustacea and has evolved a very effective technique in studying them. A recent paper, "On the Feeding Mechanism of Certain Marine Ostracods" (*Trans Roy. Soc Edin*, 57, Part 3, No. 30; 1933), concerns *Asterope* and *Cypridina* and the comparison of their mouth parts. Also those of *Cytherella* are described. *Asterope* is a purely filtratory feeder with a perfect filter apparatus; no large particles are taken and there are no labral glands, the labrum being very small. *Cypridina* feeds both on large food masses and on minute detritus which it abstracts from the water in the same way as *Asterope*, but the labrum is large, with a labral gland the slimy secretion of which entangles the food particles, and there are biting jaws Prof. Cannon believes that the asteropids are probably derived from some detritus-eating cyprinids, *Asterope* being extremely specialised. *Cytherella* is a purely filtratory feeder, the mechanism being of a similar type to that of *Asterope*, but the processes are carried on by different limbs.

Plankton of the North Sea. Mr. R. S. Wimpenny in his paper "Variations in North Sea Plankton, 1923–24" (Ministry of Agriculture and Fisheries. Fishery Investigations, series 2, vol. 13, No. 3. 1933) studies the plankton of six stations running from Flamborough Head, east by north, to the "S.W. Patch" of the Dogger Bank. This is in accordance with the recommendations of the plankton section of the Conseil Permanent International pour l'Exploration de la Mer at Copenhagen in September 1932 "that the importance of the range of variation be kept in view". In addition, some work is included bearing on seasonal variation on the "Hydrographic Line" cruises across the whole North Sea in 1923 and the spring of 1924 The importance of the edges of marine banks for supporting a rich diatom flora is shown, especially the Dogger Bank, where there was more phytoplankton than on the Flamborough line towards the shore. Peridinians always followed diatoms, *Ceratium* being very abundant. It is pointed out that those organisms which store fat as food reserves are thus succeeded by those which store carbohydrates This has a notable physiological aspect. The distribution of *Calanus*, *Apherusa* and *Themisto* suggests their dispersion around the North Sea from west to east. The following recommendations are made. (1) a general investigation of the life-cycle of each important species individually, and its feeding habits over a wide area; and (2), a study of the direction and speed of currents in the area by direct comparison of current measurements and plankton

Parasites of Carrion-infesting Flies. Observations on the morphology and biology of some hymenopterous parasites affecting blow-flies of the genera *Lucilia* and *Calliphora* form the subject of a recent paper by Mr. A. C Evans (*Bull Entomol. Res*, 24, pt. 3). As regards the braconid *Aphaereta*, its behaviour in relation to its hosts suggests that the fore tarsi play an important function in egg-laying and possibly contain receptor organs of a tactile or other nature The eggs of *Aphaereta* increase their volume 2,900 times between the time they are laid and when they are ready to hatch. Nourishment for the rapidly growing embryo is stated to be obtained by its diffusion through the chorion of the egg As regards *Alysia manducator*, there is but little increase in the size of the developing egg. The modifications resulting from a gradual change from an ectoparasitic to an endoparasitic life, as revealed in the larvæ of the several genera studied, are discussed in some detail. In *Alysia* the egg can successfully develop when withdrawn from the body-cavity of its host, while the newly hatched larva bears a pair of open mesothoracic spiracles and closed rudiments of spiracles on the seven following segments. From these facts, and other structural features, such as the presence of a cocoon, the author concludes that the endoparasitism of *A. manducator* is a recent acquirement or, at any rate, has not reached the advanced condition displayed in other endoparasites of the same hosts. In a third parasite, *Habrobracon brevicornis*, which is an ectoparasite, the spiracles remain open throughout larval life, locomotory spines and protuberances are present and a well-developed cocoon is formed

Arizona Cacti. The first Biological Bulletin of the University of Arizona Bulletin (4, No. 3) contains an account of the Arizona cacti by W. P. Stockwell and L. Breazeale. It is a non-technical compilation based on Britton and Rose's standard work, primarily intended to facilitate identification and prefaced by a short illustrated account of the vegetative and floral parts of a cactus. A feature of the work is the large number of illustrations; line drawings of joints and spines accompany the keys to the genera and species, and photographs of most of the seventy-seven species described are included. Points of interest connected with the form and usage of the species are included in the generic and specific descriptions given in the body of the work: thus *Carnegiea gigantea* is recorded as reaching a height of forty feet and an age of 150–200 years.

A New Genus of Phycomycetes. Whilst investigating certain fungi which attack snapdragon plants, Mr. C. G. C. Chesters found a peculiar fungus which produced chlamydospores in abundance, and also thick-walled spores which were often bicellular ("A Phycomycete associated with a Diseased Condition of *Antirrhinum majus*", *Trans. Brit. Mycol. Soc.*, 18, part 3, 199–214, December 1933). The fungus produces spiny chlamydospores in the host plant and also on all the numerous kinds of culture media which have been used. The formation of the thick-walled spores is described, and shown to be roughly similar to the development of zygospores, though there are important differences. No thick-walled spore has yet been germinated, and it is supposed that the fungus represents an intermediate stage between Zygomycetes and other groups of the Phycomycetes. The organism cannot apparently be included in any existing genus, so the euphonious name of *Azygozygum chlamydosporum* nov. gen. et sp. has been suggested.

Origin of Apple Varieties. In a genetical investigation of cultivated apples, Messrs. Crane and Lawrence (*J. Genetics*, 28, No. 2) have obtained important results bearing on the production of new varieties. Many of the crosses between varieties produce few viable seeds and most of the resulting seedlings are lacking in vigour owing to aneuploid chromosome constitution. Among 50 varieties, varying degrees of self-incompatibility were present, but only two failed entirely on selfing. Certain varieties and crosses also produced albinotic seedlings. With this exception, intergrading variation was the rule as regards such fruit characters as skin and flesh colour, size, shape, flavour and time of ripening, indicating the presence of polymeric factors. It is known that many common varieties of apple are triploid, the remainder being diploid, none tetraploid. The n number of chromosomes is 17, while in most other Rosaceæ $n = 7$, or in certain genera 8 or 9. Various views of the origin of $n = 17$ from the lower numbers are held, based on the secondary pairing of the chromosomes and other evidence, but all are agreed that some of the chromosomes are present several times, thus giving a basis for polymeric factors and graded inheritance. Such well-known varieties as Baldwin, Blenheim, Gravenstein and Ribston have $3n = 51$ chromosomes. From Vavilov it appears that wild apples occur widely in Asia. He reports that in the Caucasus the fruits are small, while in Turkestan a great range of size and quality occurs, some wild trees bearing fruit of excellent flavour and large size.

Air Currents Around the Rock of Gibraltar. In *Geophysical Memoir* No. 59 of the Meteorological Office, J. H. Field and R. Warden describe "A Survey of the Air Currents in the Bay of Gibraltar, 1929–30", but the investigation, which was undertaken owing to accidents to aircraft in the lee of the Rock of Gibraltar, was confined to the disturbances set up by easterly winds, these being of the greatest practical importance to aviation. The work divides itself into two distinct sections; first, experiments with a model of the Rock on a scale of 1 : 5,000 in a wind tunnel at the National Physical Laboratory, and secondly the study on the spot of actual wind currents at different heights with the aid of pilot balloons and kites, in order to form an idea of the extent to which the system of currents observed in the wind tunnel corresponds with reality. The unusually large figure for the scale ratio model : actual (a ratio somewhere between 1/10 and 1/200 is usual in work of this kind) made this practical verification the more necessary, but it was found that on the whole the indications of the model were reliable in so far as they gave a correct picture of the directions of the different currents and of the types of permanent or temporary eddy set up. Great turbulence extended for fully two miles to the west of the Rock in easterly winds, from sea-level up to at least a height of 5,000 ft. The system of vortices included two that were large and permanent for a given wind direction, and with a shift of wind from due east there was generally a corresponding shift of the areas of danger, and at the same time changes in the permanent vortices. For the immediate purpose of the inquiry—the avoidance of further accidents—the most important item in the work is probably the map showing the positions of the danger areas for different wind directions, but there are many items of interest to meteorologists; for example, the conclusion that the obstruction caused by the Rock in a wind of only Beaufort force 6 caused vertical velocities of about twenty-five miles an hour for short periods. The conclusion was also reached that in such investigations the use of a kite balloon for a single day can give more information than many months of pilot-balloon work.

Action of β- and γ-rays on Rock Salt Crystals. When crystals of rock-salt (and many other substances) are exposed to β-rays, γ-rays or X-rays, they acquire a new spectral absorption band (giving a characteristic colour) and a photoelectric conductivity when illuminated by light frequencies within this band. Burbidge (*Proc. Camb. Phil. Soc.*, 30, Part 1) has made experiments on this effect. Using small exposures to the activating agent, he found that the photo current obtainable died away with time, so that in a few minutes he could collect all the charge that the crystal was capable of carrying. If the crystal is left in the dark, the 'activation' gradually decays, but in any event the number of electrons collected is only of the same order as the number of β-particles or γ-quanta absorbed. This is peculiar, since it is known that ultra-violet light of quantum energy 5 volts will cause activation and the β particles have, of course, energies of 10^5–10^6 volts. It is suggested that the activation is confined to comparatively rare centres such as foreign atoms or micro cracks. During the activation, a large number of electrons are disturbed from their normal levels to the lattice conduction levels, but except at such singular points, they rapidly revert to their original state. At the singular parts they revert to comparatively stable intermediate levels from which they can be raised by the absorption of blue-light quanta. Further work is contemplated—it would clearly be very interesting to determine the efficiency of activation for ultra-violet radiation of comparatively low quantum energy.

Thirteenth Annual Report of the Forestry Commissioners*

THE Forestry Commission is in its second decade For the work proposed for the decade it had been estimated that a sum of about 11¼ million pounds would be required, working receipts were estimated at £2,160,000, the net contribution from the Exchequer being £9,115,000 The chief works to be carried out were the afforestation of 353,000 acres and the establishment of 3,000 workers' holdings For the purposes in view it would be necessary to acquire each year 6,000 acres of plantable land and 2,500 acres of agricultural land These proposals were subject to a severe cut at the hands of the May Committee in the interests of economy (NATURE, Sept 17, 1932, p 427) As a result of subsequent discussions between the Commissioners and the Chancellor of the Exchequer, the latter undertook to provide annually for the next five years a sum of £450,000, this with working receipts giving the Commissioners about £600,000 annually for forestry operations

Changes of policy in Government departments other than that dealing with forestry, however admirable their main aims at retrenchment may be, often result, in the first instance, in unavoidable losses In the case of forestry, sudden fluctuations of policy, justified apparently by the necessities of the Exchequer, are particularly liable to lead to loss and waste. In the present case, where so large an amount of the work of the Forestry Commission is planting and the provision of the plants required annually for the estimated area to be afforested, a serious annual curtailment of the land to be planted up would of necessity be followed by a drastic decrease in the number of plants required for the purpose. This inevitable result was foreseen at the time the recommendations of the May Committee were accepted and at the subsequent discussion between the Commission and the Chancellor of the Exchequer. Questions asked in the House of Commons on the subject in July last appeared to show that the unavoidable outcome in this respect had not been appreciated The Report for 1932 thus alludes to this important matter, and merits putting on record

"It will be appreciated that the sudden change in the Commission's planting programme could not be made without waste The material losses are most apparent in respect of nursery plants. In view of all the facts it was decided to retain in the nursery only those surplus plants which were within the economic limit of age [four years old] and, further, did not necessitate additional expenditure in weeding, etc. There has thus been a destruction of surplus plants beginning in the nursery season 1932 and not yet at an end. When the readjustment has been completed it is estimated that the cost price of the plants involved will amount to approximately £50,000"

The net total area acquired in Great Britain to September 30, 1932, was 709,008 acres, of which 439,885 acres were classified at the time of acquisition as plantable Of the plantable area 265,275 acres (60 per cent) are situated in England and Wales and 174,610 acres (40 per cent) in Scotland The total area planted or sown during the year was 22,663 acres, of which 21,277 acres were placed under conifers and 1,386 acres under broad-leaved species. Included in the above are 522 acres reafforested in the former Crown woodlands and 182 acres replanted after damage by fire The 'Cost of Planting' still unfortunately remains at a high figure. It is stated that "The outlay per acre on labour and material on the areas planted between 1919 and 1932 was as follows. England and Wales, £9 3*s* 0*d*.; Scotland, £9 15*s* 1*d*; Great Britain, £9 7*s* 3*d* These figures cover the cost of preparation of ground, drainage, fencing, plants, planting, replacement of failures and weeding but do not include expenditure on forest protection, overhead charges and supervision." Perhaps 'Cost of Formation' would be a better term than 'Cost of Planting' for operations which cover a great deal more than the mere 'planting'

The total addition to the forest area of Great Britain during the year was 16,927 acres In forming plantations and beating-up previous years' plantations 51,600,000 trees were used, of which 39 per cent were Norway and Sitka spruces; 32 per cent Scots and Corsican pines, 14 per cent European and Japanese larches, and 3 per cent Douglas fir An area of 242 acres of existing woods was underplanted, necessitating the use of 217,000 plants

Grants to private individuals and local authorities for planting and scrub-clearing (on the basis of £2 per acre for planted conifers and £4 per acre for approved hardwoods to be maintained thereafter as forest crops, and £1 per acre for clearance of scrub on areas of not less than 20 acres) amounted to £11,710, advances in respect of a proceeds-sharing scheme to £1,483 and overhead and supervisory charges to £3,148

In connexion with afforestation schemes generally, many countries are now interested in the question of the annual production of seed of a varying number of important timber trees, both conifer and hardwoods, the failure of a seed year of an important species becoming of almost world-wide importance. In this matter the British Empire has an interesting record, for it is many years since interchanges or gifts of forest tree seeds were started between Australia, India and South Africa, to mention three countries only. The competition in modern times for the seed of certain species has become greater and this applies more especially to some of the temperate conifers such as Sitka spruce, Japanese larch and so forth With this competition the prices of seed of certain species have risen considerably It is pleasant to recognise that inter-Empire and international courtesy results in handsome gifts of seed being made by one country to another On this interesting matter the report has the following: "The only seed which had to be imported from North America was Sitka spruce from the Queen Charlotte Islands · Japanese larch could not be obtained from Japan. Norway spruce and European larch were in abundant supply from the Continent, but only a moderate quantity of Corsican pine was procurable. As regards Great Britain, Scots pine seed was plentiful, but requirements of European larch could not be met; seeds of hardwoods with the exception of ash were again scarce" The Commissioners acknowledge their thanks for gifts of seed from the forest authorities of Bulgaria, France, Greece and Portugal

---

* Forestry Commission Thirteenth Annual Report of the Forestry Commissioners for the year ending Sept 30, 1932. Pp 43 (London H M Stationery Office) 9*d* net

Acquisitions of land on a reduced scale were sanctioned, as also the inauguration of a certain number of forest workers' holdings Acquisitions of land during the year amounted to 81,933 acres, of which 46,437 acres were classified as plantable, whilst 115 holdings were completed during the year, the total number now amounting to 1,156 at an average cost per holding of £499

The balance in the Forestry Fund at the commencement of the forest year was £446,432 Receipts from Parliamentary votes (£447,000) and forestry operations (£151,466) amounted to £598,466 Payments amounted to £761,220, so that the balance in the Fund at the end of the year was £283,678

During the year the Commission lost Lord Lovat, its first chairman, and Mr H A Pritchard, assistant commissioner for England and Wales This thirteenth annual report may be regarded as a most fitting memorial to Lord Lovat, to whose remarkable energy and enthusiasm, supported by a strong body of commissioners and a keen staff, the present position of forestry in Great Britain must be ascribed

Racial Distributions and Archæology

IN a lecture delivered in January last year at the John Rylands Library, Manchester, and recently available (*Bull* John Rylands Library, vol 17, No 2 Separates, Manchester University Press, 1s net) Prof H J. Fleure puts forward a tentative correlation of the evidence of archæology, human palæontology and ethnology Prof Fleure aims at showing that certain phases of culture may be associated with certain physical types of man in the past, and that, subject to the reservation that modification of culture may have taken place from outside, this association still holds good in modern representatives of, or approximations to, these ancient physical types He also suggests the possible lines along which races have attained their present distribution

Homo sapiens and *Homo neanderthalensis* clearly were differentiated at an early date The former is known from East Africa, the latter essentially belongs to Eurasia In the Old Stone Age, the flake implement is associated generally with Neanderthal man, while the finer technique of the core implements points to it being the work of *Homo sapiens* The distribution of the core implement suggests that it may have arisen in Africa or south west Asia and spread, on one hand to India, and on the other to western Europe

The rise of hunting differentiates the work of the men from that of the women, the latter continuing to be food gatherers Among modern food gatherers and hunters are the pygmy peoples of Africa and south east Asia Their breadth of head is possibly an ancestral trait derived from extinct types of man, such as Neanderthal man, whose heads incline to brachycephaly, if the torus is ignored Unfortunately, no ancient skeletons of pygmies are known On the other hand, a majority of the representatives of early *Homo sapiens* have long heads and most of the characters of the one of the two types into which these can be differentiated, are found among primitive hunter and collector groups, such as the jungle tribes of India, the Veddah of Ceylon and the Australian. The Bushmen and the extinct Tasmanian also include a good proportion of extreme long heads, as also do the Eskimo. These two groups may represent two early drifts of man, pushed to the farthest corners of the earth, while the pygmies took refuge in the equatorial forests

There are numerous groups in which most have moderately long heads, while a few have extremely long heads These are common in Africa, around the western Mediterranean, in North Africa and a related type is found in the Deccan of India, while much the same may be said of large groups in the East Indies. All are essentially herdsmen or cultivators African groups show that hunter men acquired cultivator women The herdsman grew from the hunter Herding made men more predominant than ever and increased their pride in their breed Cultivation first arose in north-east Africa and south west Asia, perhaps in India as well, and there may have been a primary spread thence to the west and south east The spread to the south in Africa encountered difficulties of climate and the cultivator remained essentially a woman It is, therefore, probable that much of the stock whence springs the pygmies was handed down in Africa, while in south-east Asia, there are traces, if rare, of this early stock, and the inhabitants of Papua have kinky hair It seems useful, therefore, to think of a gradation with an increase in importance of the older types and style of life as one goes south in Africa, or through south-east Asia to Papua, while the absence of cultivators in Australia and Tasmania points to the isolation of these two areas before the arrival of cultivators in Papua

North of this area of culture and drift lies the mountain mass of Tibet with its westward extensions North of this the ways would be open only after the last glaciation. The north-eastward drifts through Asia, continuing into America, belong to a Tardenoisian or late Capsian phase

In this connexion the rise and spread of broad-headed man must be considered The main area of distribution is the mountain zones of Asia, Anatolia and Central Europe Tentatively it may be suggested that the type came into existence in south-west Asia, in or near the Anatolian peninsula Knowledge of ancient skulls is still insufficient to say when these broadheads moved into Central Europe, but there are broadheads from an epipalæolithic station at Ofnet, and from the beginning of the Bronze Age there is a peasantry in Central Europe Some of the peoples of the Pamirs are broad-headed and in other respects like the people of Central Europe. It is difficult not to suggest a common intermediate origin for the two In Anatolia and the western part of the Balkan peninsula there is a very broad-headed type with very straight occiput This may be a specialisation which has superseded the older form

Farther east and associated with the high plateau of the Gobi is a different intensification of broad-headedness, the most marked form being that with the face flattened, oblique eyes, yellow-brown skin and lank hair.

It is possible that these broad-headed types spread in the early days of the development of cultivation. There was evidently an important spread of population about the middle of the third millennium B.C. in and around the great steppe, which reached north China and may be responsible for some of the drifts to America.

So far as the steppes of western Asia and southern Russia are concerned, the broad-headed type was not the earliest in the population The graves of the third millennium yield a majority of extreme long heads, differing from the hunter and collector people surviving farther south. This type spread into Europe from the early Bronze Age onwards Later in the Bronze Age came a period of warmth and drought which leaves the steppe poor in remains and probably accounts for the small extent to which inter-tropical Africa was influenced by Bronze Age movements. The Bronze Age movements distributed skilled craftsmen with a high grade of organisation far and wide; while as regards the steppe the movements had acquired the driving power of the acquisition of the horse Hence their movements were turned towards Iran and India, in directions in which conditions were suitable, rather than to the north-east. These peoples are generally credited with being the authors of the Aryan languages Their relation to the people of the Old Stone Age is not clear.

There remains a long-headed element, or rather on the long-headed side of medium, found in western Europe, as for example in Britain and eastern Asia, notably in China. There are indications of a spread of early agriculturists through south-eastern Asia to north China, which included moderately long-headed elements as well as broad-heads; and this element may also have been included in a similar migration to western Europe, but lack of data precludes dating.

Industry and the Research Associations

ON March 22, the Department of Scientific and Industrial Research convened an important conference at the Institution of Civil Engineers, at which Lord Rutherford presided, and more than one hundred representatives of the twenty-one research associations formed under the auspices of the Department were present The object was to provide an opportunity for frank discussion with officers of the Department and members of its Advisory Council on the present position of the research association movement and its future

On the eve of the conference, Sir Kenneth Lee, who is a member of the Advisory Council closely identified with the work of the research associations, and whose firm belief in industrial research is well known, entertained the representatives to dinner at the Dorchester Hotel. Mr. Runciman represented the Government and many prominent men in industry, finance and in the Civil Service were present Among the speakers were Mr. Runciman, Lord Rutherford and the Right Hon. Reginald McKenna. In the course of his remarks, Mr. Runciman read a statement from the Lord President of the Council, in which Mr Baldwin said that those present no doubt shared the opinion of the Advisory Council that the present scale of operations of the research associations is totally inadequate if they are to serve their full purpose He looked forward, with confidence, to industrialists improving matters in that respect, especially now that the prospects of trade are more promising. If they do so, Mr. Baldwin's message continued, they can rely on the Government on its side being prepared to play some part in the forward movement and to help in extending the scale of operations.

The views expressed at the conference left no doubt that the Advisory Council of the Department is right in believing that the time is ripe for a great development in the research association movement. The associations have already made a deep impression on British industry, not only in producing practical results of great monetary value, but also in bringing about a more sympathetic attitude towards the usefulness of scientifically trained men in the works. Several speakers emphasised the paramount duty of research associations of carrying out long-range investigations essential to widening the boundaries of knowledge Reference was made to the benefits conferred on the consumer by the improvement in products as regards utility and price and to the raising of the standard of living resulting therefrom, and for this reason it was urged that a continuation of a substantial contribution from Government sources is fully justified Attention was also directed to the importance of achieving stability of finance for the research associations as a means of securing the best work from those employed by them, of ensuring that the best scientific brains are available for that purpose and of making possible the planning of long-distance programmes.

At the conclusion of the proceedings, Lord Rutherford referred to the statement made by Mr Runciman the previous night on behalf of the Lord President as to the willingness of the Government to afford increased financial help, and urged that as a next step the councils of the research associations should consider the scale of work required to meet the needs of their particular industries and submit proposals for the consideration of the Department, in order to bring about at the earliest possible date a very different scale of operations

University and Educational Intelligence

CAMBRIDGE.—The following appointments have been made: Dr. W. A. H. Rushton, of Pembroke College, to be University lecturer in physiology. Mr O A Trowell, of St. John's College, to be University demonstrator in physiology and Dr H. N. Green to be University demonstrator in pathology

LEEDS.—The following appointments have recently been made: Dr Douglas H. Collins, to be research fellow in rheumatism under the scheme of co-operation between the University of Leeds and the Harrogate Royal Bath Hospital, for the institution of research into the cause and cure of chronic rheumatism and allied conditions; Dr. W A. Bain, to be lecturer in physiology

THE Educational Advisory Board of the British Social Hygiene Council is proposing to form a permanent central exhibit of biological teaching material and apparatus. In view of the increasing demand for including biology in school curricula, such an exhibit should prove useful to teachers The Board is therefore seeking suggestions in connexion with all forms of biological material. Further information concerning the proposal and a list of suggested headings under which information is sought can be obtained from Mr. Percy F. Lee, Education Officer, Educational Advisory Board, British Social Hygiene Council, Carteret House, Carteret Street, London, S.W.1

Science News a Century Ago

A Charter for the University of London

At a Court of the Common Council of the City of London held on April 3, 1834, the Lord Mayor stated that he had received a request, numerously signed, calling on him to convene a special meeting to consider the propriety of presenting an address to His Majesty praying that a charter might be granted to the University of London. A supporter stated his belief that the King and Ministry agreed in the desirability of granting the charter, and that the signature of His Majesty would have been put to the charter had not a petition against it been presented by the University of Oxford. It was urged against the proposition that Oxford, Cambridge, and other colleges never had the power of conferring degrees until they had gained a high reputation for ecclesiastical and scientific learning. The speaker looked upon the University of London as a mere joint stock company, and stated that he held in his hand a £100 share of the University of London, which had been sold that very morning for £23. He proceeded to ask how the Corporation could be justified in going to the King for a charter for a concern the shares of which were sold for £23 apiece. The motion to present an address to His Majesty in favour of granting a charter to the University of London was carried without a division.

Paris and London Geographical Societies

The Paris Geographical Society was founded in 1821, that of London in 1830. From the time of institution of the latter, the two bodies were on most friendly terms, and exchanges of courtesies were frequent between the respective officers.

The French society was itself considerably assisted in its early years through the co-operation of the reigning house. On January 1, 1834, the president, M. le duc Decazes, with many members, waited upon the King and Queen at the Palace of the Tuileries, and were received in audience for an hour and a half. The heir to the throne, the Duke of Orleans, was also present, and various State functionaries. In an address to the King, the president alluded to the interest of the Duke of Orleans in the Society. The King in his reply confirmed his own good wishes and desire to secure for France the honour of geographical discovery. An address to the Queen followed.

On April 4, 1834, at a general assembly of the Society, it was announced that the Duke of Orleans had offered a prize of 2,000 francs to the navigator or traveller whose geographical observations and results should be useful to agriculture, or in the industrial arts, in the course of 1834 and 1835. At this assembly, also, the award of a gold medal was decreed to Capt. John Ross for his recent discoveries and additions to geographical knowledge. (*Bull. Soc. de Géog. Paris*, ser. 2, vol. i.)

Surrey Zoological Gardens

The Surrey Zoological Gardens on the south side of the Thames in London were opened in 1831 by Edward Cross, who had previously had a menagerie at Exeter. On April 5, 1834, the *Times* announced that "a most important addition has just been made to the already valuable collections in these gardens, in the acquisition of a fine young rhinoceros, the only one of the species which has been in this country for the last 20 years. . . The great value attached to the possession of a living specimen of this animal, and the difficulty in procuring one may be inferred from the fact that the cost of the present, from the time it was taken in the Birman Empire, and the charge of its food and conveyance to England have exceeded 1000£ though it is yet little more than a year and a half old." After describing the animal, its food and its habits, the *Times* said. "The present specimen, owing to its youth, is as we have already stated, very harmless, and will follow in a fawning manner those who feed it, yet we understand that as it approaches to mature age its native fierceness will break out and will not tolerate the familiar approach of man, nor at times can its keeper enter its den without considerable danger. The last rhinoceros in this country was so fierce that it could not be exhibited until it was secured in its den by very heavy chains."

Death of Baron de Lesseps

On April 6, 1834, Jean-Baptiste-Barthélemi, Baron de Lesseps, the traveller and diplomatist, died suddenly at Lisbon at the age of sixty-eight years. For many years he had represented France, first in Russia and then in Portugal, and had held a post in Moscow previous to the disaster of 1812. He was born at Cette on January 27, 1766, and in 1785, when La Pérouse was fitting out the frigates *Boussole* and *Astrolabe* for an expedition to the Pacific, de Lesseps was appointed to accompany him as interpreter. The ships left Brest on August 1, 1785, doubled Cape Horn, visited the shores of California and in January 1787 reached Macao. Thence they proceeded to the coasts of Tartary and Kamtschatka, and at Avatska de Lesseps was sent home overland with the journals of the voyage, the journey across Siberia and Russia taking about a year. In December 1787, La Pérouse, leaving the north, called at the Friendly Islands and in January 1788 sent home from Botany Bay his last letter. Thirty-eight years later the remains of his ships were found by an English captain in the Queen Charlotte Islands. In 1790 de Lesseps published a journal of his journey from Kamtschatka, and in 1831 enriched with notes an edition of the "Voyage" of La Pérouse.

Mrs. Somerville Honoured

In 1831 Mrs Somerville had published her "Mechanism of the Heavens" and in the beginning of 1834 her "Connexion of the Physical Sciences". These works gave her a place among the most eminent women of science of all time. She was honoured by various scientific societies and on April 6, 1834, Mrs Marcet wrote to her from Geneva: "I am desired by Professor Prevost to inform you that you were elected an honorary member of the Société de Physique et d'Histoire Naturelle de Genève on the 3rd April, and that a diploma will be forwarded to you by the earliest opportunity. After all the honours you have received, this little feather is hardly worthy of waving in your plume, but I am glad that Geneva should know how to appreciate your merit. You receive great honours, my dear friend, but that which you confer on our sex is still greater, for with talents and acquirements of masculine magnitude you unite the most sensitive and retiring modesty of the female sex; indeed, I know not any woman, perhaps I might say any human being, who would support so much applause without feeling the weakness of vanity. Forgive me for allowing my pen to run away with this undisguised praise, it looks so much like compliment, but I assure you it comes straight from the heart, and you *must* know that it is fully deserved." Mrs Marcet was the author of "Conversations on Chemistry", which Faraday said "gave me my foundation in that science".

Washington, D C

National Academy of Sciences (*Proc*, 19, 991–1058, Dec 15, 1933) L Harris, W Jost and R. W B Pearse Separation of hydrogen isotopes by diffusion through palladium Hydrogen, produced by passing steam from 'electrolysed water' containing 1 part in 1,000 of heavy isotope over heated iron, was passed through an electrically heated palladium tube The gas was enriched in the heavier isotope 5–8 times when the pressure was reduced from 750 mm to 39 mm, and a further 1 5 times when it was reduced to 8 mm. Thus a ten-fold increase in concentration is produced at one stage The method is not considered as likely to compete with the electrolytic method, except in special circumstances. Theoretically it suggests that diffusion of hydrogen through palladium is an atomic process and that there is an activation factor operating in favour of the heavy isotope Harlow Shapley and Jenka Mohr: Summary of a variable star survey in an external galaxy. A survey of Cepheid variable stars in the Large Magellanic Cloud As a whole, about 1 5 per cent of the supergiants between absolute magnitudes − 1 and − 4 are Cepheid variables. The most numerous periods are 2–3 days, and no important correlation exists between amplitude of variation and luminosity or period The diameter of the Cloud is about twelve degrees and its linear diameter not less than 15 000 light years HENRY NORRIS RUSSELL and DONALD H MENZEL The terrestrial abundance of the permanent gases Although nitrogen is one of the most abundant elements in stars and nebulæ on the earth it forms 0 02 per cent only even of the superficial material A theoretical discussion leads to the view that the so called permanent gases were mainly lost by escape into space within a short time of the birth of the earth as matter ejected from considerable depths in the sun HARLOW SHAPLEY On the linear diameters of 125 large galaxies Nothing comparable in size to our galaxy has been found (diameter 30 kiloparsecs) The average galaxy is a little less than 2 kiloparsecs in diameter the Large Magellanic Cloud is comparable with the mean of the 125 largest systems in 25 selected groups New values are derived for distances and mean density of matter in these groups W E CASTLE and HANS NACHTSHEIM Linkage interrelations of three genes for rex (short) coat in the rabbit Three races of these rabbits with abnormally short soft and plush like hair and curly whiskers have arisen in recent years by a recessive mutation in a different gene The genes responsible for two of the mutations are in the same chromosome (10–12 per cent crossing over) but the other is in a different chromosome These races may become important commercially for their pelts W E CASTLE The gene theory in relation to blending inheritance Generally speaking alternative characters (gene determined) characterise individuals blending characters are more fundamental and characterise species genera and families The cytoplasm of the egg affords a mechanism (for example the organiser of the amphibian egg) for the transmission of such blending characters though genes borne in chromosomes may modify them The present assumption that they are determined indirectly by genes is unproved M DEMEREC The effect of X ray dosage on sterility and number of lethals in *Drosophila melanogaster* Working under standardised conditions induced sterility and frequency of induced lethals are approximately proportional to dosage HARRY H LAUGHLIN The specific formula of heredity MARCUS M RHOADES (1) A cytogenetical study of a reciprocal translocation in *Zea* (2) A secondary trisome in maize G H PARKER The colour changes of elasmobranch fishes Two skates indistinguishable in colour became lighter and darker respectively when placed in a white and a black tank Changing the fish over reversed the changes one assuming a pinkish hue Two to twelve hours was required for the changes EDWIN B WILSON On overlap PAUL S EPSTEIN On the temperature dependence of ferro magnetic saturation The theory of ferro magnetism deduced by the author in 1932 fits very well data published by Allen and Constant which lead to the rule that the ratio of saturation intensity at any temperature to that at the absolute zero plotted against the ratio of temperature to Curie point for all ferro magnetic crystals of the cubic system gives one universal curve J L WALSH A duality in interpolation to analytic functions by rational functions G A MILLER Groups involving a small number of squares F J MURRAY A theory for * operators analogous to the theory of reducibility for self adjoint transformations in Hilbert space

Discovery and Invention

THE importance of scientific research in the modern State no less than in industry encourages discussions from time to time as to the mechanism of discovery and the best means of encouraging it Dr Lampitt for example in a recent address on fundamental problems of the food industry stressed the importance even in industrial research of a true spirit of inquiry the lack of which was liable to lead to unsound work which later investigators would invalidate In stressing the importance of the spirit in which problems are faced he had in mind chiefly however the importance of a critical attitude towards experimental methods and published results he uttered a much needed warning against the tendency to assume the validity of such results and the adequacy of an experimental technique without any rigorous verification of its suitability for the particular purpose in mind

It is unfortunately true that the critical spirit is not so general a characteristic of the young research worker whether in industry or in academic work as is desirable but this is only one indication that scientific training sometimes fails to impart the scientific spirit or the secret of scientific method A discussion recently held by the Institution of Mechanical Engineers starting from a group of papers on invention and the inventor made a valuable contribution in this field by its attempt to elucidate the mental characteristics of the successful inventor—an attempt in which we have made singularly little progress since the days of Francis Bacon

Some of the chief inventions upon which modern industrial development is founded such as the steam engine the power loom printing and gun powder were all made by persons working independently of scientific research It is true that the discoveries of science enlarged the bounds of invention and opened up much more fruitful fields for the inventor but the technique like the motive of discovery differs essentially from that of invention This is so widely true that the adequacy of invention as a basis of industrial progress is questioned by some shrewd observers who look instead to the much wider use of scientific methods in the acquisition and application of new knowledge

It is interesting in this connexion to note that Dr Lampitt attributed the unsatisfactory position of our knowledge of food problems partly to the use of hit or miss methods Such methods have occasionally been successful, as witness Charles Goodyear's discovery after ten years of such haphazard work that sulphur was the agent necessary to effect vulcanisation They are too prodigal of time and money to be applicable under the team work conditions prevalent in modern industry, and the firm or industry which clings to them is destined speedily to be outstripped by its competitors

Without providing us with a full philosophy of discovery, the discussion to which we refer although relating mainly to invention is highly suggestive in material from which such a philosophy might be evolved or at least in stressing factors to be cultivated in the training of those undertaking a career of scientific research The importance of accurate observation and experimental ability need no further discussion They have been accepted since Galileo's day as the basis of scientific research and Bacon's exposition of the possibilities of the scientific method assumed their use in the formulation and verification of hypothesis

The importance of an accurate knowledge of the present position as a starting point if duplication of effort is to be avoided should be obvious, but the importance of sifting that knowledge is often missed, as is the danger of paralysing initiative through excessive knowledge of detail At this point our modern examination system exercises some of its most baneful effects Only a clear understanding of what is involved in the scientific method and a firm grasp of its essential principles, can enable the young investigator to day to find his way through the literature bearing on his problem and avoid alike the mortification of merely repeating some previous work and the deterring or deadening influence of massed knowledge Creative science is as dependent as creative art upon a sense of values and upon intuition linked to imagination

The further suggestion was made that youth is an important factor in creative work By this we must understand the resilience and alertness of mind which are characteristic of those between twenty five and forty years of age, but by no means their monopoly Beyond that age, maturity of judgment and experience tend to be offset by habits of conservatism and complacency, not to mention the bondage of the preconceived idea from which comparatively few are able to free themselves So far as science is concerned, however, rash is he who attempts to fix an age limit beyond which brilliant discovery and creative thought are rare and unexpected On the contrary, Bavink pointed out quite recently that the really important discoveries in modern science are mainly the work of those who have long been at a position of eminence in their chosen field

If the charge of grooviness or lack of receptivity can rarely be brought against the real leaders of scientific thought, the important contributions which have come from those outside the industry in which the discovery or invention finds scope is a significant reminder of the value and inspiration which a fresh outlook may possess This is true not merely of scientific discovery but of invention also Benjamin Huntsman was a clock maker whose desire for better steel for his springs constrained him to invent crucible steel Henry Gort was a navy agent when he invented the puddling process for wrought iron and Arkwright was a barber before he applied himself to the problems of spinning

To the influence of professional organisations which may at times impede progress we have recently referred, but there are other personal qualities which are important The ability to utilise the literature without being suppressed by it is largely dependent on a capacity for assimilation which in genius is often limited to a narrow field The born organic chemist may be almost unteachable as regards mathematics, and a mechanical genius may find electricity a sealed book

The place of initiative in the make up of the investigator has already been emphasised The capacity for concentrated effort is another important factor and while a capacity for taking infinite pains does not constitute genius, genius is rarely without that capacity, at least in directions which serve its ends Moreover, this capacity for concentrated effort is closely related to that desire to see the work executed in the most thorough and efficient way which is an essential part of the scientific spirit

There are many other qualities which are to be found or desired in the scientific investigator and which condition his success whether in industrial or in purely scientific work In both, the capacity for co operation is of growing importance Both classes are required, though in varying degree, to co-operate with other workers, sometimes in different branches of science, in an attack on a 'common objective' Both are sometimes concerned with enlisting the interest and support of those possessing merely traditional or practical knowledge ; and both are also interested in the wider dissemination of the new knowledge, particularly in our technical schools.

To get a more scientific basis into industry, particularly our traditional industry, involves close co-operation between the man of life-long experience and the scientific worker. Such co-operation has a cumulative effect. It does far more than merely assist in the conduct of the industry on scientific lines, the solution of fundamental problems, or the reconciliation of art and industrial practice and craftsmanship The new problems it throws up provide a continual and invaluable stimulus to the scientific worker, which of itself is likely to yield rich fruit in the creative work which it incites.

Rontgen, and the Discovery of X-Rays

Wilhelm Conrad Rontgen and the Early History of the Roentgen Rays By Otto Glasser With a Chapter *Personal Reminiscences of W C Rontgen*, by Margaret Boveri Pp xii+494 (London John Bale, Sons, and Danielsson, Ltd , 1933) 32*s* 6*d* net

LOOKING backward we can see very clearly the monumental character of the discovery of the X-rays by Wilhelm Conrad Rontgen in November 1895 This was truly the beginning of the 'new physics' and the first of a series of profound and basic revelations, which even now show no sign of ending It is given to few men of science to make discoveries which attract world-wide and lasting attention, but the X-rays with their amazing penetrating powers, and their immediate and beneficent application in medicine, made an appeal to men of science and laymen alike, which is not likely to be surpassed in our time Röntgen's discovery in fact, as Sir J J Thomson remarked in his Rede lecture on July 10, 1896, "appealed to the strongest of all human attributes, namely, curiosity"

The recent publication of a biography of Röntgen by Dr. Otto Glasser is a timely reminder of very stirring days. At the period of his discovery, Prof. Röntgen was in his fiftieth year, and held the position of director of the Physical Institute of the University of Würzburg He was born at Lennep, in the German Rhineland, but his early youth was largely spent in Holland, to which country his parents emigrated when he, an only child, was three years old He had a chequered school life at Utrecht, which ended in his taking up at the age of twenty years the study of mechanical engineering at the Zurich Polytechnic School Three years later he obtained his Ph D and was appointed assistant to Kundt, who had succeeded Clausius in the chair of physics at Zurich Kundt's friendship helped to settle Rontgen's future career for him, and he accompanied Kundt when the latter was called to Wurzburg and afterwards to Strassburg At the age of thirty-four years, Rontgen was appointed professor of physics at Giessen, and nine years later (in 1888) succeeded Kohlrausch at Wurzburg

Rontgen's interests were spread over a wide range of physics, though most of his published papers dealt with heat and general physics He devoted, however, considerable attention to pyro- and piezo-electrical effects in crystals, and in 1888 he conducted important fundamental investigations which established the magnetic effects resulting from the motion of a dielectric between two electrically charged condenser plates Rontgen's outlook on physics was thoroughly classical and his natural bent for exact experimental work, which had been strengthened by the influence of Clausius, remained with him all his days He made little use of mathematics, but got his results with ingenious and simple equipment much of which he constructed himself He greatly appreciated an ability to improvise apparatus, and held the view that a man should be able to make everything really necessary with a pocket knife It is, therefore, not surprising that he normally dispensed with the services of an assistant and preferred to make his own observations

Rontgen had been at Wurzburg some five years when, in the early part of 1893, Helmholtz (then president of the Reichsanstalt) in a remarkable paper published in *Wiedemanns Annalen* in 1893, predicted the properties of electromagnetic waves of various lengths, and *inter alia* forecast a high penetrating ability and small refrangibility for waves of atomic dimensions There is no evidence, however, that Rontgen was influenced by this paper when in October 1895 he decided to make some experiments with cathode rays Rather would it appear that he was attracted by the contemporary work of Hertz and Lenard on electrical discharges in evacuated tubes Following Lenard's practice, Rontgen completely enclosed the discharge tube within black paper The room was darkened and Röntgen, who was working alone late in the evening, saw a small piece of paper painted with barium platino-cyanide and lying on the bench, shine out brightly. This was on Friday, November 8, 1895 Röntgen kept his own counsel for several weeks, apparently telling neither his staff nor his wife, who could find no explanation of his lateness for meals, his lack of appetite, his ill humour, his complete absence of conversation and his hurried returns to the laboratory Rontgen was, in fact, slowly convincing himself by repeated experiments that he was not the victim of hallucination and that here was a new type of radiation with penetrating powers which appeared incredible He presently came to appreciate the full significance of his discovery, and with the remark to his wife "Now the devil will be to pay" released his momentous announcement in the form of a preliminary communication "On a New Kind of Rays" which he presented to the Physical Medical Society of Wurzburg at the end of December during the Christmas recess.

This paper was printed and circulated prior to reading. In it Rontgen clearly identified the source of the "X-rays", as he styled them, with the region of impact of the cathode rays on the glass walls of the tube He also established the dependence of the penetrability of the rays on the density and thickness of the obstacle, their properties of exciting fluorescence and affecting a photographic plate, the absence of regular reflection or of appreciable refraction (the refractive index of water was less than 1 05), the absence of magnetic deflection, etc He inclined to the view that the rays were longitudinal vibrations in the ether. The paper was supplemented by shadow pictures of many objects, including the bones of the hand

Röntgen sent copies of his paper and X-ray pictures to a number of friends, including Sir Arthur Schuster at Manchester, who wrote an article on the rays in the *British Medical Journal* of January 11, 1896. The news of the discovery first reached London on January 6 and was thence cabled the world over Rontgen's paper was speedily translated into many languages. NATURE first referred to it on January 16, and followed this up with a translation of the complete paper on January 23. Mr. Campbell Swinton appears to have published in January the first X-ray photograph taken in Great Britain. On January 27, Sir J. J. Thomson described his experiments on the X-rays to the Cambridge Philosophical Society, experiments which, one recalls, speedily led him to the study of gaseous ionisation and conduction, followed a year later by his discovery of the electron. The world acclaimed another monumental discovery, and the Cavendish Laboratory, under its famous chief, became a magnet for the physicists of every land

Among other British X-ray pioneers were Sir Oliver Lodge, Lord Blythswood, Prof A W. Porter, Dr J MacIntyre, Prof Silvanus Thompson, Sir James Mackenzie Davidson and Sir Herbert Jackson, each of whom made important contributions The first journal in the world to be devoted exclusively to X-ray matters was founded in Great Britain by Sidney Rowland in May 1896, under the title of *Archives of Clinical Skiagraphy*. This is now the *British Journal of Radiology* The British Rontgen Society, which was founded in 1897, was also the first society to be originated in any country with the object of studying the X-rays Röntgen was one of its first honorary members.

Dr. Glasser's arresting book includes many examples of the amazing interest excited in the public press, both popular and scientific Ludicrous misconceptions prevailed in many quarters The new rays would render privacy impossible The *Pall Mall Gazette* in March 1896 referred to the "revolting indecency" of it all and called for legislative restriction of the severest kind Mr *Punch* found repeated inspiration in the rays for both rhyme and cartoon. The most fantastic stories found credence, despite openly voiced scepticism in some quarters of any semblance of truth in the discovery. Reams of sensational matter emanated from Edison's laboratory in America. "he and his staff worked through seventy hours without intermission, a hand organ being employed during the latter hours to assist in keeping the force awake". Fortunately the pace was too hot to last, but until the general fever of excitement had abated, the new rays became in many countries the tool of the charlatan, who exploited them as his fancy lay, whether in the direction of alchemy, vivisection, spiritualism, telepathy, soul photography or soothsaying.

On March 9, 1896, Rontgen submitted his second communication to the Würzburg Physical Medical Society. He refers to the superiority of a platinum target as a generator of X-rays and the successful use of a concave cathode and a 45° target (a design which Crookes had developed in 1879 for other purposes). He remarks on the usefulness of a Tesla transformer as a means of exciting an X-ray tube. Most of the memoir is devoted to the action of X-rays in discharging electrified bodies in air.

A year later (March 10, 1897) Röntgen published his third and last memoir. He remarks on the scattering of X-rays by air, on the general uniformity of emission of X-rays from a tube in different directions, on the different penetrating powers of rays from 'soft' and 'hard' tubes, on the gradual hardening of X-ray tubes with use, etc

After his third memoir Rontgen published little more on X-rays He left Würzburg in 1900 for Munich, where he resumed his early researches on the physical properties of crystals Laue's famous crystal diffraction experiments on X-rays in 1912, followed by those of the Braggs, must have afforded Röntgen great gratification He himself had unsuccessfully tried to reflect and diffract the rays, and he also lived to see in 1922 A H Compton specularly reflect X-rays from glass and silver at tiny glancing angles In 1924, a year after Röntgen's death, Siegbahn and his coadjutors prismatically refracted the rays, the angle of deviation for a glass prism amounting to only a few seconds of arc, the refractive index being less than unity, as forecast by the classical Drude-Lorentz theory of dispersion In 1925, A. H. Compton and Doan successfully diffracted the X-rays by the use of ruled gratings on speculum and extremely small glancing angles The nature of the X-rays was long the subject of controversy, but these several experiments all played their part in finally establishing the position of the rays as radiation with wave-lengths of the order of atomic magnitude.

For some years distinctions were lavished upon Röntgen, but his essential modesty and shyness remained unaffected He refused to derive any financial advantage from his discovery, nor would he consent to lecture either to the Reichstag or the British Association. He received jointly with Lenard the Rumford medal of the Royal Society. He declined the title 'von', and the offer of the presidency of the Reichsanstalt in 1904 The first Nobel prize for physics was awarded to him in 1901, and in his will he left the prize to the University of Würzburg, but this together with his personal fortune became valueless as a result of the deflation after the War.

Miss Boveri, a close friend of Rontgen, contributes to Dr. Glasser's book an intimate personal study of Röntgen. There is an amusing story of how Röntgen, who had an excitable temperament and had been rather spoiled as a boy, became embroiled in a terrific argument with his wife during a walk. In his anger he stopped a passing cab, bundled her into it, paid her fare home and continued his walk alone He was fond of cards, but a bad loser · he would pound the table when his hand was a poor one, and if his partner played badly he would become so angry that some of his friends refused to play with him under any consideration However, these were minor weaknesses He was kind-hearted and fond of children, and having none of his own, adopted a niece of his wife's Rontgen, who was cautious, reserved and extremely independent, did not make friends easily He was fond of outdoor life, and never lost his love of certain of the Swiss alpine resorts, where his tall athletic bearded figure was well known He had a strong aversion to motor-cars Everything he did he took up with great intensity and zest He hated speeches and rhetoric in any form and his lectures, sound and clear though they were, did not make wide appeal to his students He refused, as he said, to 'pamper' them, and the ill-prepared dreaded his examinations, because he did not regard routine questions as a test of intelligent knowledge

During the War Rontgen allowed himself to be persuaded into signing the proclamation of the 'ninety-three intellectuals' and gave up his Rumford medal to be melted for gold, but in his later and calmer years he regretted that he had been led into such matters He derived great consolation that his discovery had contributed so much to the amelioration of the suffering of the wounded among friend and foe He died in his seventy-eighth year on February 10, 1923.

Many have wondered that the discovery of X-rays had not been made long before it fell to Röntgen, for numerous workers must have produced the rays in abundance, certainly during the previous fifteen years It was perhaps inevitable, therefore, that the flood of contemporary appreciation was tinged here and there with not overkindly comment, but in looking backward we may recall with Dr Glasser the words of Kircher, a seventeenth century predecessor of Röntgen, who remarked, "Nature often allows amazing miracles to be produced which originate from the most ordinary observations and which are, however, recognised only by those who are equipped with sagacity and research acumen, and who consult experience, the teacher of everything".

Physical Chemistry of the Proteins

Handbuch der Kolloidwissenschaft in Einzeldarstellungen . Herausgegeben von Prof Dr Wolfgang Ostwald Band 6 *Kolloidchemie der Eiweisskorper* Von Prof Dr Wo Pauli und Dr Emmerich Valkó Zweite völlig neu bearbeitete Auflage Pp xiv+353 (Dresden und Leipzig Theodor Steinkopff, 1933) 28 gold marks

THE first edition of this monograph was published in 1920, since that time there have been important developments both in the theoretical and the practical aspects of this subject, among which may be mentioned the conception of the amino acid as a *zwitterion*, the general adoption of the activity notation, the measurements of molecular weights of proteins and the application of the interionic attraction theory of strong electrolytes to protein systems

In the preparation of the second edition, Prof Pauli has been assisted by Dr Valkó, who is joint author with him of the larger textbook "Electrochemie der Kolloide" The authors are to be congratulated in that they have gone far towards the achievement of the purpose set forth in the general preface to the series of monographs by their general editor, Prof Wo Ostwald, namely, that the publications should serve the purpose of collecting and correlating papers on the subject of colloid science that are widely dispersed through an extremely large number of diverse journals The authors have amassed data from physical, chemical, biological and technical publications, and the mode of presentation is much to be commended, in that the results under discussion are largely given in the form of tables and curves, and diagrams descriptive of the technique employed are provided in many cases

The chapter in which the mobilities of protein ions are discussed is of special value, as it includes a description of the methods and results of Tiselius, which were published in a journal difficult of access. The section dealing with the hydration of proteins is a lucid and discriminating summary of the subject, in which special prominence is given to the interesting researches of Sørensen, of Weber and of Moran

The reference made to the work of Sørensen, Linderstrøm-Lang and Lund is rather brief in view of its importance. Their paper included the first definition of the isoionic point, and a comprehensive study of the effects of salts on the ionisation of proteins The studies of gas and electrolyte equilibria in the blood, published by Van Slyke and his colleagues, have been omitted.

It is to be regretted that the second chapter, entitled "The Chemistry of Proteins", should be so short, and that allusion to the stimulating papers of Max Bergmann should be restricted merely to references The hypothesis due to K H Meyer and Mark, that the protein molecule consists of a long main valence chain, is given greater prominence Reference is made to Meyer's hypothesis that protein exists in solution in the form of aggregates or micelles In the light of Svedberg's work on the constancy of the molecular weights of proteins over a range of protein concentrations described in Chap xiii, it would seem that the aggregation theory cannot have an universal application Svedberg has shown, moreover, that in the case of many proteins, the sedimentation velocities agree with those calculated for spherical molecules

The recent investigations of Sørensen and his colleagues on the fractionation of proteins, and the solubilities as affected by the mass of the solid phase, are described in Chap vii Sørensen has concluded that purified proteins are not chemical individuals, but systems of components which dissociate reversibly The solubilities of fractionated globulins indicate that the solid phases may be complexes of eu- and pseudo-globulin

Many tables of data relating to the physical properties of proteins, including their dielectric constants, have been given, a very considerable part of this material is not available in any other textbook on proteins. As an inclusive summary of recent investigations in this field, the handbook of Pauli and Valkó should be most useful to those interested in the physical chemistry of the proteins.

G S. ADAIR

Micro-organisms and Insects

L'Infection chez les insectes . immunité et symbiose. Par Dr. A Paillot Pp 535. (Lyon · Librairie médicale et scientifique, 1933) 100 francs

DR A PAILLOT has devoted a number of years to the study of the diseases and other microbic infections of insects. In the present work he reviews various aspects of insect microbiology and incorporates the result of his own researches The broader theoretical problems of immunity and symbiosis are discussed at length, while the morphology and biology of a large number of disease, and other, organisms are clearly described and figured This volume is not an exhaustive treatise on its subject, such an aim was not the author's intention The reader will find some phases more fully treated than others, while certain aspects are omitted, or come in for very cursory mention

The book is divided into seven parts of these, the first four parts deal respectively with maladies of protozoan origin, fungal diseases, diseases due to viruses and to bacteria The fifth part is concerned with anti-bacterial immunity and its phases among insects The author discusses at length the subject of natural and acquired immunity and concludes that they are due to both cellular and humoral reactions He considers, however, that the experimental evidence shows that the reactions of the blood plasma itself are of greater importance in this aspect than cellular, or phagocytic, activities

Part six is a very full account of symbiosis in various species of aphides Symbiosis is not discussed with reference to other insects since the author's original observations are concerned with the group just mentioned This part includes a very full account of the cytology and the transmission of the specific micro-organisms from generation to generation of their hosts The biochemical side of the subject is not discussed and we are still in the dark as to the nature of the mutual reactions that are involved Dr Paillot elaborates the interesting theory that symbiosis in aphides has developed from bacterial infection The micro-organisms, he claims, have been able to establish their permanent relationship owing to a progressive diminution of their virulence, so that they have become completely inoffensive and ultimately beneficial Part seven is concerned with the practical side of insect microbiology The utilisation of disease organisms in pest control and their rôle in the transmission of human and animal maladies are discussed in this section

The book concludes with a classified bibliography, running to about fifty pages, together with indexes to subjects and authors' names

Short Reviews

Allen's Commercial Organic Analysis Vol 10 *Hæmoglobin and its Derivatives, Albuminoids or Scleroproteins, Structural Proteins, Examination of Foodstuffs for Vitamins, the Hormones, the Identification of Unknown Woods and Charcoals, the Pectic Substances* Editor Dr C Ainsworth Mitchell Fifth edition, revised and partly rewritten Pp xi+817 (London J and A Churchill, 1933) 32*s*

WITH the publication of the tenth volume of "Allen's Commercial Organic Analysis", the fifth edition of this comprehensive work is completed A decade has passed since the issue of the first volume of this edition and, in the interval, many branches of applied chemistry have increased in importance, even now a part of this edition is out of date, especially for data contained in the volumes published so far back as 1924 or 1925. The editor has taken advantage of the issue of this final volume to include a number of subjects of recent technical importance, so that there is no definite connecting link between the subject matter of the various chapters These new sections include such subjects as hæmoglobin, albuminoids, vitamins in foodstuffs, hormones and special wood charcoals A section on fibroids in a former edition has now been extended and includes a large amount of data on natural and artificial silk, furs, hairs and wool. Pectin substances have been given special consideration and the qualitative and quantitative examination of such substances is considered.

The reviewer has had an opportunity of checking the methods of pectin analyses given in the work and finds them very detailed and reliable In the estimation of pectin substances (p 524) there is an inaccuracy in the making up of the standard solution, and the subsequent statement that a molecule of furfural liberates exactly two atoms of bromine from potassium bromide might be expressed differently

This final volume also includes a useful 250-page subject index supplement for the whole edition The fifth edition of 'Allen' is the most authoritative and complete work on commercial or applied organic analysis which has ever been published. It is absolutely indispensable to the analyst and works chemist, and no chemical reference library will be complete without it

J REILLY.

A Handbook of Child Psychology Edited by Carl Murchison (The International University Series in Psychology) Second edition revised Pp xii+956 (Worcester, Mass · Clark University Press, London. Oxford University Press, 1933) 24*s*. 6*d* net

IF one turns over the pages of a psychological treatise written a generation or two ago, one finds that what it mostly comes to is a patient analysis of adult consciousness, the method employed being that of introspection. Experimental psychology, involving objective measurement and claiming to be scientific, was slowly making its way, and is now very extensively cultivated *Of* child psychology the same can scarcely be said. James Sully's "Studies of Childhood" (1895) was in Great Britain a pioneer book and is still quotable. But certainly not in Great Britain, nor even in the United States, has child psychology received the attention of the ablest investigators to the extent which one would have thought to be its due Therefore genetic as distinguished from analytic psychology has suffered

That progress is being made, however, is shown by the latest addition to the International University Series in Psychology So rapidly is the subject advancing that this second edition of the "Handbook of Child Psychology" bears little resemblance to the first, published little more than three years ago In twenty-four closely packed chapters the latest work on the scientific study of children is summarised, not for the general reader, but for experts, by experts As the book is of American origin it would in any case have been natural that most of the contributors should be American, but as a matter of fact it was inevitably so, because most of the research work has been done by Americans Single contributions come also from Toronto, Vienna, Berlin and Geneva, but none from Great Britain. Ten of the contributors are women, one of whom makes a remark which some of the men would do well to take to heart "Too much work upon these problems is being done with paper and adding machines, and too little with human beings"

Recent Advances in Psychiatry By Dr Henry Devine Second edition Pp xi + 364 (London J and A Churchill, 1933) 12*s* 6*d*

It is very gratifying to note a marked improvement in the second edition of this book The first edition was very good, but Dr Devine is to be congratulated on the additions and alterations he has made Three new chapters have been added, dealing with "Germinal Inheritance in the Psychoses", "Mental Disturbances in Pernicious Anæmia" and "Mental Disorders and Deficient Oxidation"

It is a very great pity that the work on toxic foci in the psychoses is practically uncontrolled There is need of the investigation of a series of 1,000 normal cases, particularly with reference to the presence of infections in the sinuses and the bowel. The work of the toxic schools is unconvincing without control.

We would like to have seen some mention of the use of diathermy in the treatment of general paralysis of induced pyrexia The use of malaria is attended by a certain death-rate due to the malaria alone The results from diathermy are just as good as from malaria, particularly if combined with tryparsamide. In the next edition, will Dr Devine give us a chapter devoted to occupational therapy, which plays such a very important part in the modern treatment of mental illness?

This is one of the best British books on psychiatry.

Handbuch der Physik Herausgegeben von H. Geiger und Karl Scheel Zweite Auflage. Band 24, Teil 1 · *Quantentheorie* Redigiert von A. Smekal. Pp ix + 853. (Berlin Julius Springer, 1933) 79 gold marks

The advances in quantum theory have of late been so rapid that most workers in theoretical physics must appreciate the publication of vol 24 of the well-known "Geiger-Scheel Handbuch der Physik" Part 1 of this volume is now available, unfortunately, it is impossible to do more than outline its contents here It contains a description of the origin and development of the older or classical quantum theory by Rubinowicz, followed by a treatment of the general principles of wave mechanics by W Pauli Bethe discusses the quantum mechanics of one- and two-electron problems, while Hund contributes a very important article on the quantum mechanics of atomic and molecular structure Wentzel is responsible for a section on collision and radiation processes, and N F Mott contributes the concluding section on the application of wave mechanics to nuclear physics The whole production is of the same high standard of excellence as its precursors

Manipulative Surgery By A S Blundell Bankart (Modern Surgical Monographs) Pp xii + 150 + 17 plates (London · Constable and Co, Ltd, 1932) 7*s* 6*d* net

If the practice of manipulative surgery is almost a monopoly of the bone-setter, the medical profession alone is to blame The art of manipulation, with its therapeutic indications and contra-indications, has received but scanty attention in the curriculum of the medical student, the average doctor's complete ignorance of the subject is not surprising Mr. Bankart's book, which is intended for the student and general practitioner, is consequently of value in two ways It demonstrates that a large field of minor orthopædic practice is well within the limitations of any doctor who cares to learn its principles and who remembers his studies in anatomy; and to the physician who does not wish to acquire the art it indicates the large number of conditions which can suitably be referred to the orthopædic surgeon, instead of being allowed to drift into the risks of treatment by the unqualified practitioner

The Blue Book, 1934: the Directory and Handbook of the Electrical and Allied Industries 52nd edition Pp 1474 + xxx (London: Benn Bros, Ltd, 1934.) 25*s*. net.

This handbook is almost a necessity to everyone engaged in the electrical industry. The handbook section contains the latest data concerning conductors and insulators. It includes a map of the completed grid in Great Britain and a list of overseas telephone routes and rates. The alphabetical, geographical, colonial and foreign sections contain information in a convenient form which would be difficult to find elsewhere.

The British Polar Year Expedition to Fort Rae, North-West Canada, 1932-33

By J. M. STAGG

THOUGH the special and continuous needs of meteorology, terrestrial magnetism and allied sciences for systematic observations over wide areas and in high latitudes had been felt long before 1882–83, it was not until then that a large-scale effort was made by twelve countries to study events in those subjects through a full year according to an agreed plan. In collaboration with Canada, Britain's share in that First International Polar Year, as the twelve months ending August 1883 has come to be called, was to equip a party under Capt Dawson, R E, for continuous observations in meteorology, terrestrial magnetism and aurora to be carried out at Fort Rae, a trading outpost of the Hudson's Bay Company on the Great Slave Lake, North-West Canada Practically and scientifically, from the point of view of international collaboration as well as that of Britain's own participation in it, the year's activities were completely successful

As the jubilee of that First Polar Year approached, it was felt in many quarters that no time could be more appropriate for a repetition on a much more extensive and intensive basis In the three primary subjects then investigated, advances in recent years have been large, and mainly all in the direction of indicating that further progress depended on the gathering of more precise observational material from a still wider field and to the limits of the atmosphere The sequences of weather changes over limited regions like Britain in moderate latitudes might well be determined by conditions in the stratosphere far to the north or south, days or weeks ahead the short-period irregular changes in the earth's magnetic field, known to be intimately associated with the state of ionisation in the conducting layers of the high atmosphere, seemed to be bound up with auroral activity on one hand and the interruption of long-distance wireless communication on the other To a few even it has seemed not improbable that these two domains, the apparently locally determined meteorology and the more cosmically produced aurora and its effect on the earth's magnetic field through the intermediary of the ionosphere, might be interconnected. Such were the questions in many cases speculation and theory had outstripped fact.

So in 1929 the time was ripe for the proposal of a Second Polar Year for 1932–33. An International Polar Year Commission was set up with the directors of the meteorological services of many countries as members and Dr. la Cour of Copenhagen as its president. National committees were constituted to carry out the general recommendations in each country. In Britain, with Sir Henry Lyons as its chairman, and Dr. G. C. Simpson as secretary, the National Polar Year Committee has had representatives from the Royal Societies of London and Edinburgh and from six other interested institutions A grant-in-aid of £10,000 by the Government through the Air Ministry has been the primary source of supply for the Committee's activities, though many manufacturing and wholesale firms have contributed to the fund by generous gifts of food and instrumental equipment and even of money

Britain's share in the international programme has been fourfold

(1) The provision of new instruments and facilities for conforming to the general plan of observations at some permanent meteorological stations and observatories in the country as well as on ships at sea

(2) An intensified programme of auroral observations and photography in Scotland and in the Orkney and Shetland Islands.

(3) An extensive and novel series of observations on the variation in height and intensity of ionisation of the conducting layers in the high atmosphere, by Prof E V Appleton and his party at Tromsø

(4) The equipment and manning of a station at Fort Rae, Canada, for complete and continuous observations in meteorology, terrestrial magnetism, aurora and atmospheric electricity

The Fort Rae party under J M Stagg comprised Messrs W R Morgans, P A Sheppard, and W A Grinsted (Meteorological Office) with Mr A Stephenson (Cambridge) as observers, and Mr J L Kennedy as mechanic and steward. With sixteen tons of instrumental and foodstuff equipment, the party left England in May 1932 and journeyed by the usual route to Edmonton, Alberta, thence northerly for about a thousand miles, using the Hudson's Bay Company's river transport for the trip down the Athabasca and Slave Rivers, and so across the Great Slave Lake to its northern extremity The site of the station was reached by the middle of June

To ensure that all the instrumental equipment would be in full running order and the routine of observation thoroughly established by August 1, the starting date for the overlapping 'year' of thirteen months, every minute before then was required for erecting special huts and getting the autographic recording instruments in action. These covered every one of the main aspects of meteorology and terrestrial magnetism, and included a new type of magnetograph designed at Copenhagen, in which the variometers for the force components were optically compensated for temperature changes, and with a recorder arranged so that the time of incidence of sudden changes in the magnetic field could be read with an accuracy of two seconds. It is of interest to note that, using this magnetograph, a 'sudden commencement' of a magnetic disturbance on April 30, 1933, was judged to appear practically simultaneously at places so far apart as Copenhagen, Thule (in north-west Greenland) and Fort Rae

Nearly all recording instruments were run in duplicate to make sure that the records would be as complete as possible, the secondary records in most cases providing the additional safeguards of furnishing data with other characteristics, as, for example, a more open time-scale or lower sensitivity

As part of the programme of meteorological work, more than four hundred pilot balloon ascents were made during the term of occupation of the station and twenty-eight *ballons sondes* were sent up The hydrogen for this work was manufactured on the spot in a new apparatus designed at the Airship Works, Cardington, and was produced by the interaction of granulated silicon with heated caustic soda Two of the instruments from *ballons sondes* released in winter with surface temperatures about -30°C attained heights of 16 km In both cases, the base of the stratosphere was very well marked at 8 5 km and with temperatures about -60°C

With Fort Rae in an exceptionally good position relative to the zone of maximum auroral frequency, much importance was attached to the observations and photography of aurora for precise determinations of its height and orientation To a substation (which was actually the site of the station in the First Polar Year fifty years ago) some 25 km to the south-east, a telephone line was erected allowing photographs of the aurora to be taken simultaneously by cameras specially designed for auroral work in Norway From these pairs of photographs, some 4,700 of which were taken by the party during the stay at Rae, it is hoped to obtain much definite information about aurora in that part of Canada Although the period was so near the minimum of the present cycle of solar activity, aurora was observed at some time on every night when conditions were practicable It was not infrequent during the winter months for aurora to continue almost uninterruptedly for fifteen hours

In addition to the activities in these, the main lines of investigation, observations in atmospheric electricity claimed much attention Continuous records of the potential gradient of the earth's electric field near the surface were maintained autographically, and frequent measurements of air-earth current and small ion content of the air were made Experiments were also carried out to determine the nature of the diurnal variation of these quantities and also of the rate of production of ions near the ground

The winter conditions at Rae during 1932–33 were characterised more by the steadiness of the cold than by extremes of temperature reached Over the seven months ending April 30, 1933, the average temperature was -20°C, but the lowest average for any single month was only -31°C — January and February were almost the same in this—and the lowest daily mean was only -40°C During the short warm summer, daily temperatures frequently exceeded 20°C

The party returned from Rae in September and early October 1933 with a very large amount of observational matter for further study It is now the intention that each country participating in the international programme should make all its data available by reduction and publication as early as possible, so that the larger and more important task of co-ordination of the results from all the stations may not be delayed In many ways it was unfortunate that the Second Polar Year should have coincided with times of such grave financial stringencies in so many countries But the difficulties encountered in the preparations both by the International Commission responsible for the general organisation of the Polar Year activities and by the individual national committees in each country served to emphasise the value of the work It is certainly illuminating that forty-six different countries have taken part in the programme in one way or another, and of these, twenty-three have set up extra stations—in many cases more than one—either within their own territory to extend the number of their regular observatories, or outside their own lands as temporary observation posts

---

Progress of Industrial Research

IN a recent address Dr F A Freeth made an eloquent protest against the habit in Great Britain of always classifying science as something apart from ordinary life It would be difficult to imagine a document better fitted to demonstrate the essential place of science in our ordinary everyday life, or to inspire a general confidence in scientific workers and science by the public, than the eighteenth annual report of the Department of Scientific and Industrial Research * Published within a couple of days of Dr Freeth's address, the report describes contributions made by the work of the Department to every major need of our social and industrial life. The comparatively small sum of £654,736 (gross) or £451,987 (net), which represents the expenditure of this Department for the year ending March 31, 1933, represents also a contribution to the efficiency of every department of State and to the recovery or the prosperity of many industries, the true value of which it is impossible to assess in cash, but which repeatedly has earned dividends many hundred-fold on the expenditure involved

Even this expenditure, however, represents a further decrease on that recorded in the previous report—£695,677, the actual expenditure in 1931–2 being £543,700 Receipts, however, increased from £160,977 to £202,749, thus exceeding those of 1930–31 (£184,829) Expenditure on the National Physical Laboratory was £195,316, against which receipts amounted to £90,854 , on the Chemical Research Laboratory, £18,406 net , Forest Products Research, £32,286 net , Fuel Research, £84,226 net , Radio Research, £11,340 net , water pollution, £8,642 net and Headquarters Administration, £24,791 net Against expenditure of £44,583 on Food Research, a grant in aid of £30,133 from the Empire Marketing Board assisted to bring the net expenditure to £10,774 Receipts of £7,380 bring the expenditure on Building Research to £34,663 net, while the £46,140 balance of the Million Fund brought the Grants for Research to a total of £51,700 net

---

* Department of Scientific and Industrial Research Report for the Year 1932–33 (Cmd 4483) Pp iv+189 (London H M Stationery Office, 1934) 3s net

A large part of the report of the Advisory Council, over Lord Rutherford's signature, which precedes the summary of work, is devoted to a discussion of the 'million fund' to which reference has already been made in NATURE of January 20, p 77 The same report, however, also refers to the transference to the Department from the Ministry of Transport of the responsibility for the direction and supervision of road research This is a matter of direct concern to every citizen whether he uses the roads in his own car or in public vehicles The traditional methods of road making were designed to provide a surface sufficiently firm to prevent slow-moving horse traffic from sinking appreciably in wet weather Despite the revolutionary changes which have taken place with surprising success in the last thirty years, we have still very little scientific knowledge either of the foundations of the road or of the materials of its superstructure such as will ensure that a success in one place can be repeated in another A systematic programme of research has been prepared, covering not only the testing of the materials but also the processes involved in road construction, maintenance and use One of the most important requirements for success in laboratory investigations is correlation between behaviour in practice and the results of laboratory tests Such correlation in road work is a protracted process, as the information from practice is obtained only after the road has been in existence many years Results from road tests at the Harmsworth Experimental Station, for example, are incomplete after 3½ years of heavy traffic, and to accelerate progress attention is being given to the development of road testing machines

Other work bearing on transport is also being carried out by the Department The Chemical Research Laboratory is investigating the properties of road tar, while investigations to discover the most suitable traffic signal beams have been carried out at the National Physical Laboratory, the results of which, after tests on signals in actual use at Reading and in Oxford Street, London, have been embodied in a British Standards specification Other work at the National Physical Laboratory on motor-car headlights has led to a method of determining the light distribution which should be aimed at for a headlight beam

The National Physical Laboratory has also been concerned with other methods of transport Its Aerodynamics Department has been responsible for much important work bearing on the design of new types of aeroplane and particularly on stability and control of aeroplanes, including an investigation on the spinning properties of typical aeroplanes The corrosion fatigue of certain aircraft materials has been studied by the Engineering Department, the Sound Division has rendered assistance in connexion with the acoustical features of aircraft design The recent series of aviation disasters alone should indicate the great importance of work on systems of direction-finding which is proceeding under the Radio Research Board

Research on the design of hulls and propellers for ships carried out on models at the William Froude Laboratory, dealing with the influence of waves on the resistance, propulsion and pitching of ships has reached a stage when the general effects of rough water upon the hull resistance are known Such progress has been made with the study of the action of a screw propeller when propelling a ship in a rough sea that performance can be predicted with confidence from model tests In addition, investigations have been carried out to determine the effect of wind forces from any direction on the steering of ships

Particular stress is laid on timber research in the Report of the Advisory Council The work carried out in the Forest Products Research Laboratory covers the working and finishing properties of wood, as well as its natural durability and its resistance to insect or fungus attack, which is of widespread importance to the builder of houses or maker of furniture, etc It is, however, only one link in a chain which connects the forest in the Empire Overseas with the timber user in Great Britain The other two links, information on prices and supplies and marketing promotion, are seriously threatened by the disappearance of the Empire Marketing Board, and upon their continuance much of the utility of the research on timber depends

Timber naturally suggests building and the work of the Building Research Station provides many illustrations of the influence of scientific research on the comfort and efficiency of the home These include investigations on factors influencing weathering, a study of the most economical means of heating a house, which indicated the superiority of the intermittent method, investigations on plasters, on the problem of damp walls, the exclusion of solar heat by thin roofs, on painting on cement and plaster Other contributions in this field come from the work of the Research Associations Such, for example, are those dealing with frost-bursting of water-pipes of various materials, with methods for preventing the corrosion of galvanised hot-water tanks or the dulling of bright metal surfaces used in architecture, both inside and outside buildings. Investigations on earthing to eliminate risks of electrical shock have continued: a comprehensive survey of causes of radio interference due to the operation of electrical equipment is proceeding, while at the National Physical Laboratory the transmission of sound through partitions or double windows is receiving attention with a view to better design of rooms and houses, nor should we overlook the work which is being carried out on steel frame buildings.

A method of determining the efficiency of hot plates is being standardised, and the discovery of a means for reducing the temperatures reached by gas-filled lamps in show-case and shop-window fittings has definitely reduced the risk of fire in stores where inflammable goods are displayed

So much of the work of the Department has a direct bearing on public safety and health that its activities can quite legitimately be summarised as that of a great national life assurance department In addition to the industrial examples already given, space allows us to mention only two. the metallurgical research dealing with the factors causing the cracking of boiler plates and the work carried out on the production of a more efficient respirator for use in industrial processes as a protection against the inhalation of dust. From a more general point of view may be cited the search of the Chemical Research Laboratory for new drugs efficacious in the treatment of sleeping sickness in Africa, or the work on atmospheric pollution and water pollution.

Such a dry year as 1933 emphasises the importance of the latter field, and the report itself points out that two recent serious outbreaks of enteric fever in Yorkshire were both due to comtaminated water supplies Frequently the condition of streams and rivers cannot be improved sufficiently until satisfactory methods of reducing the amount or polluting nature of various domestic or trade effluents have been devised Since new types and sources of pollution are always arising, as, for example, the effluents from modern milk depots or factories, the department concerned is continually charged with fresh programmes for investigation.

The whole of the important food investigations carried out under the Department have a profound bearing on the national health. The quality of foodstuffs is continually being improved and waste eliminated bv means of better methods of transport and storage One effect of such work is to make possible a steadily rising standard of living. The Food Investigation Board has been responsible for work covering the storage of meat by freezing or chilling, the transport of bacon from Australia and New Zealand, the freezing and smoke-curing of fish, the gas-storage of apples, the storage of fruit for canning, and much effort is being given to the development of appropriate methods of studying the damage which fungi, etc, can produce in fruit and other foodstuffs The Flour Millers' Research Association has undertaken investigations designed to place the conditioning of flour on a scientific basis and is studying the effect of added oils and fats on the baking quality of the flour The Cocoa, Chocolate, Confectionery and Jam Trade Research Association has materially assisted in improving the making of marmalade, jams and jellies by its study of pectins, and has studied the development of means of combating insect pests of nuts and chocolates and other confectionery in retail shops and of remedying defects which develop in chocolate-covered wafers and candied peel. An outstanding investigation of the Food Manufacturers' Research Association has been the development of an instrument for determining the amount of salt in any part of a piece of meat during curing, and in consequence allowing of closer control of the process

Some will be surprised to learn that important dental research is being carried out under the Department, including the determination of the best composition of amalgams for dental purposes and the properties of widely-used dental rubbers, or that as a result of studies on aluminium paint made by the Paint, Colour and Varnish Manufacturers' Research Association it is possible to indicate the conditions which must be observed to avoid the loss of brilliance or other special properties

The relation of such research associations as those of the cotton, woollen and linen industries, or the Launderers' Research Association to our everyday needs is equally impressive The first, for example, has provided the industry with a new method for the rapid separation of good cotton from dust and other foreign matter The second has developed a method for treating the fibres in bulk before spinning, whether for woollen or worsted processes, which renders them unshrinkable, besides giving lustre and softer handling, thus eliminating the prickly feeling which sometimes causes discomfort in wearing woollen goods The same Association is developing reliable scientific tests for judging the fastness of dyed woollen fabrics to light and other agencies.

The Linen Research Association has not only established the causes of the comparatively rapid wear of double damask on laundering along lines near the selvedges but has also found a method modifying the cloth structure so as to enable it to withstand the laundry wear. The Launderers' Research Association has been responsible for tracing the cause of the development of holes in collars for which ordinary wear could not account and, as a sequel, for co-operation with the manufacturers to eliminate the defect. Moreover, the arrangement by which certain manufacturers have agreed to submit new fabrics to the Association for examination of the laundering properties before putting them on the market is one the importance of which to the public is obvious

Through the work of the Department, science is contributing not merely to industrial efficiency and safety, to public health and safety and social welfare, but also to a steady rise in the general standard of living and in the quality of the service rendered by our interdependent industries.

Obituary

PROF. DAVIDSON BLACK, F.R.S

THE untimely death of Prof. Davidson Black, which occurred on March 15 at the age of forty-nine years, deprives the Cenozoic Laboratory of Peking of its honorary director, who had unique qualifications of knowledge, temperament and technical training to make him the ideal man for such a position Not only had he in high degree the competence and personal qualities for the work, but he also had the enterprise and courage boldly to pursue the adventurous policy which has met with such conspicuous success When he entered the University of Toronto, Prof A B Macallum recommended him before entering the Faculty of Medicine to acquire some general training. Acting on this suggestion, Davidson Black studied anthropology and took an arts degree After qualifying in medicine he became instructor in anatomy in the Medical School of the Western Reserve University at Cleveland, Ohio At the end of 1913 he was made assistant professor of anatomy under Prof Wingate Todd, and after his marriage he came to England and worked at comparative neurology in my department in the University of Manchester

At that time I was working on the reconstruction of the Piltdown skull and the study of the endocranial cast obtained from it, and for purpose of comparison had collected casts of all the known fossil human skulls This work aroused a much greater interest in Dr Davidson Black than the brains of the Dipnoi in which I was trying to engage his interest, and he at once made himself familiar with all of the material I had collected, and informed me that that was the kind of work to which he was determined to devote his life He at once set to work to train himself for such a career, acquiring the technical experience and studying the geological literature which was essential for the field work he contemplated His attention was arrested by the writings of a fellow Canadian, Dr William D. Matthew, at that time a member of the staff of the American Museum of Natural History in New York In particular he was fascinated by the work entitled "Climate and Evolution" which was published in the *Annals of the New York Academy of Sciences*, and this gave Davidson Black the complete conviction that China was the place where primitive man was likely to be discovered Hence in 1916 when, after his military service, he was offered the position of professor of neurology in the Peking Union Medical College, he at once accepted the offer under the conviction that it coincided with the ideas he had formed as to his career.

In Peking, Davidson Black found a group of very agreeable colleagues with whom he entered into relationships of close friendship, in particular with Dr. A. W. Grabau, the professor of palæontology in the National University of Peking, who was destined later on to suggest the name *Sinanthropus pekinensis* which Davidson Black adopted for his great discovery To the group of young geologists in Peking, Grabau was the guide and friend. His delightful dinner parties served the purpose of keeping this group *au courant* with progress of geological knowledge, and also gave them perspective and a wide outlook upon the subject. In the course of the conversations which took place at these dinner parties, Davidson Black learned of the observation made by Prof Schlosser in 1903 of the discovery near Peking of an intriguing tooth which might be that of a primitive man This served still more to deepen his conviction that Peking was the promised land of his ambition.

When, in 1926, Dr. Gunnar Anderson announced that the expedition working under his direction had found an early Pleistocene tooth, a discussion arose as to whether or not it was human Its finder was indignant that the newspapers referred to it as the "Peking Man" Dr Davidson Black did not hesitate He regarded it as a definite confirmation of the hopes aroused by the writings of Matthew and Schlosser as to the early man he had gone to China to discover In 1927 he published (in *Palæontologia Sinica*) a detailed description of the tooth which Dr Bohlin had found, and on the basis of the evidence he cited he founded the new genus and species for which, on the suggestion of Prof Grabau, he applied the name *Sinanthropus pekinensis*

The severe criticism to which Davidson Black was exposed had no other effect upon him than to make him redouble his efforts to establish the proof of the claim he had put forward, and to intensify the search for fresh material He had a little brass case made to contain this tooth which he attached to his watch chain, and he made a tour of the world trying to enlist the support of the palæontologists of Europe and America for the new genus he had created on the evidence of the tooth The excavations which were carried on at Chou Kou Tien under his direction resulted in 1928 in the discovery by Dr Birger Bohlin, working in conjunction with the Chinese geologists Dr. C C Young and Mr W. C. Pei, of fragments of two jaws in association with pieces of brain cases, and the evidence confirmed the validity of the genus founded on the basis of the tooth in 1927.

The importance of the work accomplished during the two years covered by the first appropriation of the Rockefeller Foundation led in 1929 to the renewal of the grant and the creation of a special department, the Cenozoic Research Laboratory of the Geological Survey of China, under the honorary directorship of Prof Davidson Black This significant action was due in large measure to the support of Mr. Roger Greene, the executive head of the Peking Union Medical College, of which Dr. Black was professor of anatomy The work of developing these fossils was carried out by Davidson Black himself with superb technical skill. Not only did he clean the fossils and photograph them himself, but also he made the excellent casts which have enabled workers in Europe, who could not see the fossils themselves, to form a very exact idea of their nature. The attainment of these successful results implied a very happy spirit of friendship in the team of workers who undertook the various tasks, and called for all the unselfishness and spirit of conciliation which were so conspicuous in Dr Davidson Black, and without which the spirit of harmonious co-operation would have been impossible. He was always very jealous of the honour of his collaborators, especially of the Chinese geologists. When, in 1929, the Geological Society of China created the Grabau Gold Medal to be awarded for distinguished work, and recommended him for the first award, he protested that it should go to Dr Grabau's pupil Pei, who had made the great discoveries. Greatly as he appreciated the distinction, which was made doubly attractive by being associated with his old friend and master Grabau, he felt very strongly that the leader of the field work who had found the fossils would be the more appropriate recipient. The Society, however, wisely thought better, and solved the difficulty by awarding another gold medal to Mr Pei. This incident, however, was typical of his attitude towards all his Chinese colleagues, and explains a great deal of the conspicuous success of the Cenozoic Laboratory.

Dr Davidson Black's genius for friendship really lies at the back of the great work he has been carrying on. He was a man of charming personality, of great generosity and modesty. He was as enterprising and resourceful in superintending a children's party as he was in directing the excavations at Chou Kou Tien. It was a source of intense satisfaction to him when he was invited by the Royal Society to deliver the Croonian Lecture in 1932. It was not so much any pride in receiving this high distinction, as the opportunity it gave him to describe the work in Peking in his own restrained and careful way and particularly the opportunity it offered of making adequate acknowledgment of the help he had received from others, in particular his colleagues in Peking, and when in the following year he was elected to the fellowship of the Royal Society he received this distinction with the same modesty. These genial qualities earned him the friendship of a wide circle of people of all nationalities in Peking, who are now mourning their great loss.

Prof Davidson Black's methods of work were peculiar in many respects. All his serious work was done at night time for the sake of the quiet and the freedom from disturbance which it brought. He was fortunate in having the complete confidence and support of the Rockefeller Foundation of New York, which fully realised its great good fortune in having in its service so conspicuously competent a man. With its backing, Davidson Black was looking forward to a long life time of investigation. On his way to England two years ago to deliver his Croonian lecture, he made an extended reconnaissance in India, Persia, Western Asia and Egypt to discover likely sites on which to carry out excavations for fossils of men and apes, and for several years he has lived in the hope of exploring the Sinkiang Province of Chinese Turkestan, in the conviction that he would there find fossil apes more nearly akin to man than anything that is yet known. In fact his life was devoted to the study of Central Asia, in the hope that the geographical knowledge he acquired would prove of use to him for realising his hopes. He always kept by his bedside the lives of Genghis Khan and Tamerlane written a few years ago by Harold Lamb. By saturating himself with these works he felt he was becoming acquainted with the part of the world in which his chief hopes were centred.

In taking farewell of Davidson Black one regrets not only the loss of a friend of particular charm and generosity, but also the cutting short of the brilliant work in which he was engaged, and which there is no one else competent to complete.

G. ELLIOT SMITH

Prof D M Y Sommerville

DUNCAN MCLAREN YOUNG SOMMERVILLE was born in 1879 in Rajputana, and died on January 31, 1934, in New Zealand. After receiving an early education at Perth Academy he went to the University of St Andrews, where his mathematical and scientific ability soon became apparent. In 1905 he was appointed lecturer in the Mathematics Department at St Andrews, a post which he filled until 1915, when he became professor of pure and applied mathematics in Victoria University College, Wellington, New Zealand.

While Sommerville was essentially a geometer he had considerable interests in other sciences, and it is noteworthy that the classes which he chose to attend in his fourth year of study at St Andrews had been in anatomy and chemistry. Crystallography in particular appealed to him, and doubtless these possible outlets influenced his geometrical concepts and led Sommerville to ponder over space filling figures and gave an early impetus to thoughts in a field which he made peculiarly his own. Beneath his outward shyness considerable talents lay concealed: his intellectual grasp of geometry was balanced by a deftness in making models, and on the æsthetic side by an undoubted talent with the brush. In the course of years he produced a pleasing collection of water colour sketches of New Zealand scenery.

Sommerville's mathematical work falls naturally into two parts: that of the teacher and that of the original investigator. His textbooks, which have appeared at regular intervals, are a valuable link between the old and the new era in the teaching of geometry at college. They are the "Elements of Non-Euclidean Geometry" (1914), "Analytical Conics" (1924), "Introduction to the Geometry of *n* Dimensions" (1929), and the recent "Three Dimensional Geometry" (1934), the appearance of which he did not live to see. All are characterised by a variety of algebraic treatment and a wealth of illustrations and examples, but nowhere does technical manipulation outrun the geometry The first of these, a provocative little book, appeared at a time when metrical systems alternative to that of Euclid were known only to the few It is not surprising that such a teacher carried throughout his life the esteem and appreciation of his students One of his most distinguished pupils, A C Aitken, writes of the critical time in his own student days when the University of Otago was temporarily without a professor of mathematics, and how willingly Sommerville filled the gap by weekly correspondence The written solutions and comments went far beyond what was necessary for mere elucidation

Beginning in 1905, Sommerville wrote more than thirty original papers and notes which have been published in well known journals at home and abroad The first, entitled "Networks of the Plane in Absolute Geometry" (*Proc Roy Soc Edinburgh*, 25) is typical of the sequel The main theme is that of combinatory geometry, exemplified by a systematic investigation of "The Division of Space by Congruent Triangles and Tetrahedra" (1923) in the same journal and extended to *n* dimensions (Palermo 48, 9–22, 1924) Out of this grew the work upon the relations connecting angle sum and the volume of a polytope in space of *n* dimensions (*Proc Roy Soc London*, 1927)

Sommerville was ever ready to apply his special gifts to unusual examples, as in his analysis of preferential voting and a highly original treatment of the musical scale He was also much interested in astronomy, and was one of the founders of the New Zealand Astronomical Society and its first secretary At the Adelaide meeting of the Australasian Association for the Advancement of Science held in 1924 he was president of Section A His was a life of unsparing activity, and the fruits of his work will abide There has passed from Scotland one who had already become her leading geometer of the present century

H W TURNBULL

WE regret to announce the following deaths

Dr James Mackintosh Bell, O B E, formerly of the Canadian Geological Survey and in 1905–1911 director of the Geological Survey of New Zealand, on March 31, aged fifty six years

Dr James Munsie Bell, dean of the School of Applied Science in the University of North Carolina, who has carried out important researches in physical chemistry on March 3, aged fifty three years

Prof Arthur Ranum, professor of mathematics at Cornell University, on February 28 aged sixty three years

News and Views

Caleb Whitefoord, F R S (1734–1810)

CALEB WHITEFOORD, friend of Benjamin Franklin in the hey-day of the latter's fame, was born in 1734, at Edinburgh (the exact date would seem to be unrecorded) Whitefoord was the natural son of Col Charles Whitefoord, himself the third son of Sir Adam Whitefoord, Bt, of the shire of Ayr He died on February 4, 1810, at his home in Argyle Street, in the vicinity of Soho, and was buried in Paddington Churchyard Graduating at the University of Edinburgh, Whitefoord sought London as the best field for the exercise of his varied gifts, chief among these being a faculty for satirical journalism Eventually there were few literary, scientific and political celebrities of his period outside his circle Intimacy with Franklin (they were then neighbours in Craven Street, Strand) led to the opinion that Whitefoord would make an eligible diplomatic agent for the purpose of assisting in the restoration of peace with America Accordingly, he became secretary to the Commission which concluded peace with the United States at Paris, in 1782 He was elected a fellow of the Royal Society on June 24, 1784, when Sir Joseph Banks was president A fellow of the Royal Society of Edinburgh, and of the Society of Antiquaries, London, he was a vice-president of the Society of Arts, and a member of the Philosophical Society of Philadelphia Whitefoord's portrait was painted by Sir Joshua Reynolds in the eventful year 1782, and hangs in the National Portrait Gallery, a mezzotint of this by S W Reynolds is prized A pleasing drawing (head and bust), by R Cosway, is reproduced in the *European Magazine* for 1810 In 1790 Whitefoord presented a fine portrait of Benjamin Franklin, by Joseph Wright, to the Royal Society Such interesting connexion with the Society is further emphasised by the circumstance that Whitefoord, with Count Rumford signed in 1801, the certificate of recommendation for the election of Warren Hastings

Industrial Research and the State

MR STANLEY BALDWIN, as Lord President of the Council, may be regarded as a Minister of Research, since he is responsible to Parliament for the Committee of the Privy Council for Scientific and Industrial Research He is keenly alive to the possibilities of scientific and industrial research, and this attitude marks the message he sent recently to the conference of industrial research associations, reference to which was made in NATURE of March 31, p 504 Mr Baldwin confirmed his promise on behalf of the Government in replying to a question in the House of Commons on March 27, when he said

"ABOUT two years ago, steps were taken by the Department of Scientific and Industrial Research to ascertain the views of the Councils of Research Associations connected with the Department on a proposal that powers should be obtained to require firms in an industry to contribute towards co-operative research where the large bulk of the industry was in favour of such a course. The result was unfavourable to the proposal. Evidence has, however, been received that there may have been some change of opinion in the interval and the Department propose to consult the Associations again on the subject. If it appears that there is now a consensus of opinion in favour of such a Bill and if it is the opinion that a levy for research would be found practicable in a sufficient number of cases and that advantage is likely to be taken fairly generally of the provisions of such a Bill, . the whole matter will receive sympathetic consideration by the Government."

THIS reply is encouraging, and has an important bearing on the investigations undertaken by a Joint Committee of the British Science Guild and Association of Scientific Workers as to whether the research associations should be financed by a levy on the industries concerned, or by a State grant for a limited number of years of a sum of money designed to form an endowed capital for research—such grants to be provided from the new revenue from tariffs, wireless licences or other sources

The Panda or Cat-Bear

THE arrival at the Gardens of the Zoological Society of London of three specimens of that rare and most interesting animal the panda, or 'cat-bear' (*Aelurus fulgens*), should form an addition of no small interest to those visiting the Gardens during the summer months The coloration of this animal is striking The fur is of a rich chestnut-red, with white markings on the head, and black rings round the conspicuously long tail, while the under parts are almost black instead of the normal white. Though strictly speaking a carnivore, it is nevertheless almost omnivorous For while small mammals and birds, eggs, insects and their larvæ form their principal diet, they also feed largely on fruit and many kinds of shoots, especially of the bamboo, of which they are said to be very fond. Having regard to their typically carnivorous dentition, this very mixed diet is noteworthy

THE present geographical distribution of the panda is restricted to the Himalayas from Nepal to Yunnan, at an elevation of 6,000–11,000 ft, where they haunt trees or hide among boulders as circumstances determine, emerging in the early morning and evening to forage for food. Not much is known of their habits, as may be imagined from their almost inaccessible haunts, but observations on captive specimens have revealed some interesting facts, especially in regard to their mode of sleeping. Thus at times they will curl up like a cat, turning the long tail over the head; and at times they are said to sleep standing, with the head turned downwards between the forelegs after the manner of their near relations the racoons. When excited they emit a strong odour of musk. The panda is evidently a species which is dying out, for its range in past times was vastly greater. This much is shown by the fact that a panda one and a half times larger than the existing species has been found in the English Pliocene. No fossil remains of pandas have yet been found in America. But having regard to its very near kinship with the racoons, they may yet be found.

Cane-Rats

ANOTHER addition to the Zoo worthy of note is three young cane-rats (*Aulacodus swinderianus*) from West Africa These animals attain a considerable size when adult, the body measuring nearly two feet in length, exclusive of the tail, and weigh as much as 10 lb They range from the Sudan to the Cape, and up the west coast as far as Sierra Leone. The fur is conspicuously bristly, speckled with yellow and brown. The incisor teeth are of great size and very powerful. The upper pair are marked by three vertical grooves, sufficiently deep to leave their mark on anything gnawed by those animals. They feed on roots and shoots, and sugar-cane where it is to be had.

Archæological Studies in Peru

IT would appear that the celebration, or rather the 'commemoration', to use the term preferred locally, of the fourth centenary of the Spanish capture of Cuzco, the capital of the Inca empire of Peru, has given rise to a wave of popular enthusiasm for archæology which has taken the practical form of a vote of £30,000 (according to a dispatch in the *Times* of March 27) to be expended on, *inter alia*, the establishment of an archæological institute for the study and display of Peruvian antiquities and on archæological exploration and research. Already substantial discoveries have been made in the excavation of Sachsahuaman, a site near Cuzco, where hundreds of workmen are engaged in uncovering the walls, buildings, conduits, etc, in beautifully hewn stone of this once important fortress, which has been pronounced to be the "most wonderful achievement of ancient man in the two Americas" Excavations have also been begun at Tambo-machal and Pisac, and are in contemplation at Ollantaytambo and Macchu Picchu, the last stronghold of Inca power These operations are under the supervision of the Director General of the National Museum and are being conducted in accordance with the principles of scientific archæological research. Even at this early stage, attention has been directed to the problem of pre-Inca civilisation and the opportunities which it offers for investigation. Happily the foundations for its study on scientific lines have been laid down by the work of Prof. Max Uhle and others, and if funds which hitherto have been lacking for extended exploration are now to be available, many vexed and obscure problems of Central and South American archæology will come under review. The presence of a number of distinguished archæologists in Peru during the celebrations, which began on March 23 and will go on until July 18, will no doubt guide, as well as stimulate, local effort, which is inspired by motives not entirely unmixed. Even in Peru, archæology is not immune from the spur of over-enthusiastic nationalism.

Anthropological Studies in India

IN view of the important part which will be played by racial, religious and social questions in relation to administration and government in the India of the future, considerable interest is attached to a brief survey of the work in anthropology which has been, and is now being, done in India by Rai Bahadur L K Ananthakrishna Iyer, chairman of the Board of Higher Studies in Anthropology of the University of Calcutta and the author of a number of well known works on Indian anthropology, which appears in *Current Science* of January 1934 He points out that it is only in the last fifteen years that the vast mass of anthropological material offered by India has begun to be utilised systematically The School of Anthropology in the University of Calcutta was organised in 1921, and the University is now unique in prescribing the subject for the M A and M Sc examinations The students also have the advantage of an annual course of practical instruction in the field in various parts of Bengal and Chota Nagpur when both anthropometry and cultural anthropology are studied

THE anthropological work of the University is supplemented in Calcutta by that of the Indian Museum, where there is a well equipped laboratory, and research work is also carried on Much of this research has already been embodied in important monographs Reference is also made to the work of Dr J H Hutton in Assam and to that of Sarat Chandra Roy editor of Man in India On the west coast the only institution concerned with anthropology is the Anthropological Society of Bombay , and the author expresses regret that Madras with one old and two infant universities, has taken so little advantage of its opportunities for anthropological research In Mysore, the University has revived the Ethnographic Survey of the State and the fourth and final volume of its report is now in preparation for publication The work of the Indian Science Congress is also noted The author concludes by deploring the fact that while there are many regions in India unexplored anthropologically the workers are few He urges that a band of young men should be trained to collect material in these unexplored fields

Agricultural Education in New Zealand

AGRICULTURAL research in New Zealand has a staunch friend in the Governor General, Lord Bledisloe, who, having a lifelong acquaintance with British agriculture, is peculiarly fitted to estimate the value to the farming community of such agencies as the New Zealand Department of Scientific and Industrial Research and the Cawthron Institute In a recent address to the students of Wellington College, New Zealand, on the new needs of education, he referred to the appointment of a former student, Theodore Rigg, to the directorship of the Institute, "an organization notable throughout the Empire for the thoroughness, accuracy, and economic value of its agricultural researches" Touching on the question of the careers for which a college training offers a suitable preparation, he stressed the claims of the rural population of a Dominion in which farming is the greatest industry to leadership such as a college graduate might aspire to He added point to his observations by revealing that it was considerations such as these which induced the Rhodes scholarship selection committee to select, for the first time in the history of the Trust, a young agricultural scientific worker for appointment to one of these scholarships

Investigations in the Stratosphere

THERE are now two bodies in Russia intent on surveying the scientific and other possibilities of the upper atmosphere They are the Society for Aviation and Chemical Warfare, with outside experts and with M Dubenski assistant director of the Military Aviation Academy, as chairman of the commission, and a more civilian type of composite body drawn from the Leningrad Institute of Aerology the Radio Institute and the Central Geophysical Laboratory The former organisation was responsible for the successful flight of *Stratostat USSR* piloted by M Prokofiev last September as well as that ending in disaster on January 30 this year If one can judge from the reports from Russian newspapers these two schools are sharply divided on the question of manned and unmanned balloons respectively The military organisation, the programme of which is the study of ultra violet solar radiation and atomic disintegration by cosmic rays is concentrating its attention on shock absorbers gliders parachutes, etc , in order to safeguard future crews from disaster The civil body however is specialising upon further improvements in automatic registering devices to be attached to balloonets after the manner of Regener's whose work with these down to a pressure of 22 mm (about 28 kilometres up) has not yet been superseded The new device consists of a string of two or three such elastic balloonets each about 2 metres in diameter on the ground, filled with hydrogen for carrying the self recording devices A trial has already been made with one such balloonet This reached a maximum altitude of 18 6 kilometres and was followed during its ascent by theodolite observations It automatically transmitted radio signals of pressure temperature and hygrometric data on a wave length of 25 metres Unfortunately the apparatus has been lost In a new apparatus which was to be ready by the end of March there were to be added cosmic ray intensity and gas analysis transmissions and a camera This work of the Institute of Aerology is a very laudable enterprise and the results will be awaited with interest

Sydney Harbour Bridge

AMONG the recently published abstracts of papers to be discussed by the Institution of Civil Engineers are four relating to the design, construction and calculations of the great arch bridge over the harbour at Sydney, New South Wales The papers, Nos 4904, 4922, 4923 and 4946, are by Mr R Freeman, Mr L Ennis, Mr J F Pain, Mr G Roberts and Dr J J C. Bradfield, and the discussion will be held on April 10

The bridge, which took a little more than eight years to complete, cost £4,248,000 It consists of a main span of 1,650 ft with a clearance of 170 ft over the central 300 ft of span, and ten approach spans It accommodates a roadway 57 ft wide, four railway tracks and two footways The principal parts of the main-span truss are of silicon steel with a modulus of elasticity of 30,500,000 lb per sq in Analytical methods of calculation were used, arithmetical processes being carried out by calculating machines Calculations were required for the following combinations of loads dead load, live load and impact, horizontal force, centrifugal force, wind loads and temperature variation Of the total weight of the main truss material, the proportions attributable to various loads are as follows dead weight of arch, 35 per cent, dead weight of deck, 23 per cent, live load and impact, 26 per cent, wind, 8 per cent, horizontal force, 2 per cent, and temperature, 6 per cent Tests on model members were made by means of a testing machine of 1,250 tons capacity, capable of dealing with tension and compression specimens up to 50 ft long and bend test specimens 20 ft long Tests of the arch after completion indicated a span ¾ in in excess of 1,650 ft, a difference partly due to unavoidable errors of survey and possibly partly caused by shrinkage of the concrete below the bearings The bridge was erected by Messrs Dorman, Long and Co, of Middlesborough

The *Indian Antiquary*

With the December issue, which, through labour troubles, has only just become available in Great Britain the *Indian Antiquary* ceases publication The demise of this valuable periodical will be greatly regretted by all who are interested in Indian studies For more than sixty years it has served as a medium of publication for original communications of the highest standard of scholarship, dealing with the ethnology, archæology, history, linguistics, folk lore and religions of India The *Indian Antiquary* was founded by the late Dr J Burgess in 1872 and later was acquired by the late Sir Richard Temple as his sole property Under his editorship—he was editor in chief for forty-six out of the fifty one years of his connexion with it—the services of the *Indian Antiquary* to the cultural history of India were incalculable Sir Richard Temple's wide knowledge of oriental subjects made him an ideal editor of a journal of this type, not merely because of his own numerous contributions to its pages, but also for the stimulus and assistance he was able to give to the studies of others As one result of his influence may be mentioned *Epigraphia Indica*, the official record of epigraphic work in India, which was a direct outgrowth of work initiated by the *Indian Antiquary* In 1924 Sir Richard Temple transferred his interest in the journal to a small private company, and the Royal Anthropological Institute assumed responsibility for its publication Sir Richard Temple retained the editorship, at first in association with Mr S M Edwardes, and after his death in 1927 with Mr C E A W Oldham, who became editor in-chief on Sir Richard's death in 1931 Owing to financial conditions the Royal Anthropological Institute felt compelled to sever its connexion with the *Indian Antiquary* in 1932 and during the past year it has been carried on by the editor in order to complete publication of matter in hand

Protection of Power-Transmission Plant from Lightning

A series of articles on lightning by J F. Shipley which is being reprinted in *Distribution of Electricity*, a paper published by W. T Henley's Telegraph Works Co, gives a résumé of what has been accomplished in recent years in protecting transmission lines and engineering plant connected with them from damage from lightning The effect of a lightning flash on a transmission line is to puncture the insulators or make them flash over, sometimes causing a short circuit which shuts down the supply During the last forty years a very large number of devices have been employed to protect the lines, such as air gaps, water jets, oxide films, etc These have been found only partially effective The ideal arrester would be some link between the line and earth which would have infinite resistance at the normal pressure, but when for any reason that pressure increased by 10 or 20 per cent, the resistance should become practically zero, thus furnishing the impulsive rush of electricity with a safe path to earth A recent device consists of a solid block of a material consisting of conducting particles of metallic oxide diffused in a baked clay which is microscopically porous It is similar to porcelain in texture and mechanical strength and normally has almost infinite resistance As soon as the electrical pressure across a block of it rises above a definite value its resistance decreases at a very rapid rate If we double the voltage, the current it will pass increases more than twelve times The material seems to have two names, 'thyrite' and 'ocelit' As it is an artificial product and can be accurately controlled, it looks as if a real step forward has been made in the design of these arresters, or 'safety valves' as they are often called

Electric Waxing of Floors

Helios, a German electrical trade journal printed in Leipzig, gives descriptions in three parallel columns in German, French and English respectively of the latest electrical devices In the issue for November 19 an interesting description is given of tests on an electric floor waxing device, with and without a suction apparatus for the simultaneous collection of dust The tests were carried out in the laboratories of several universities as well as in commercial test rooms When the suction device was used there was no appreciable change in the percentage of dust in the air caused by the whirling of the waxing apparatus When no suction device was employed the percentage of dust in the air increased as much as seven to eight times the normal quantity In this case the dust on the floor was whirled upwards by the waxing machine With the suction device it is not necessary to clean the room so often and there is no need to have a special vacuum cleaner. The dust which settles on furniture prolongs the work of cleaning, and certain works of art are damaged, while it is also a menace to health In many workshops the dust impairs the quality of the finished goods The floor waxing machine with suction device should prove specially useful in hotels, hospitals and sanatoriums

Industrial Physics

THE address which Dr Paul D Foote delivered before the American Physical Society as retiring president appears in full in the February issue of the *Review of Scientific Instruments* In it he points out how inadequately industrial physics has been represented on the Council of the Society, and how as a consequence much of the work of the members of the Society has failed to attract the attention of industrial executives and they are unable to see that there are places for physicists in their organisations It has been left to large corporations like the General Electric Company to show how much physicists can do for industry Dr Foote considers that the training in physics in most of the American universities fits a man neither for industry nor for a position in a junior college, and that industry has to look to the engineering rather than to the physics departments for men adequately trained in the fundamentals of classical physics in preference to those superficially acquainted with the latest developments of quantum mechanics He hopes that the newly formed American Institute of Physics and the new journal *Physics* will secure more intimate contact between physics and industry, and that the attitude of the Society towards applied physics in the next few years will insure that physics becomes a real profession rather than an academic avocation Since the foundation of the Institute of Physics, in London in 1918, the position of British physicists has improved Lord Rutherford recently pointed out that there has been a rapidly growing recognition of the importance of the physicist, not only in the academic world but also in industry, and he considers that the Institute of Physics can justly claim some of the credit for this

Tests for Accident Proneness

UNDER the title 'Tests for Accident Proneness', the Industrial Health Research Board has published the results of a further investigation into the factors involved in 'accident proneness" which have engaged its attention for several years (Medical Research Council Industrial Health Research Board Report No 68 Tests for Accident Proneness Pp iv+37 London: H.M Stationery Office, 1933. 9d net) Previous work had established that certain individuals are inherently more liable to sustain industrial accidents than others exposed to the same risk By the investigations of E Farmer, E G Chambers and F J Kirk now reported, it has been established from experiments with groups of dockyard apprentices and naval artificers that, within the groups studied, poor æsthetokinetic co ordination (defined as the ability to do certain sensori motor tests) is associated with a liability to sustain an undue number of accidents The results do not suggest that æsthetokinetic co ordination is associated with accident proneness in all occupations, although it is probably associated with it in groups doing similar work to those tested Deficiency in this function, however, only accounted for a part of the accidents sustained, and it is evident that only one of the factors involved in accident proneness has thus far been isolated and evaluated Even this, however, makes a definite step towards the practical goal of detecting beforehand those specially liable to accident and warning them against entering dangerous occupations No significant relation was observed between intelligence and accidents in any of the groups, and in two of them accident proneness did not decrease with age and experience It does not follow, however that in groups employed on different work, variations in intelligence may not play a part in accident proneness

Scientific Survey of South-Eastern Polynesia

THE Bernice P Bishop Museum, Honolulu, has organised an expedition, to be known as the Mangareva Expedition, for the study of the little known parts of south eastern Polynesia Because other means of transportation are unavailable, the Expedition is provided with two ships The *Islander* (Capt W G Anderson), a high powered sampan, was to leave Honolulu on March 1 and during a six months cruise will serve as a master ship' for scientific workers who will conduct investigations chiefly at Mangareva, Oeno, Pitcairn, Rapa, Tubuai, Rurutu, Raivavae, and Rimitara islands The second ship, the cutter yacht *Tiare Tahiti* (Capt Robert S Burrell), under charter from May until October, will serve primarily as a transfer ship' for the ethnologists at work in Mangareva and among the three hundred and sixty islands of the Tuamotu Archipelago The chief purpose of the Expedition is to record the data regarding native races, flora and land fauna, which are disappearing at a surprisingly rapid rate Incidental observations on geology, marine zoology and general oceanography will also be made The scientific staff includes Dr Peter H Buck, Kenneth P Emory and J Frank Stimson, ethnologists, Prof Harold St John and Raymond Fosberg, botanists, Dr C Montague Cooke, Jr, and Donald Anderson, malacologists, and E C Zimmerman, field entomologist Dr C Montague Cooke, Jr, has been appointed leader of the Expedition

A History of Vegetables

THE *Gardeners' Chronicle* of March 3 publishes a report of a lecture on "The Introduction of Vegetables" by Mr E A Bunyard It comes as somewhat of a surprise to find that many of our common vegetables were once regarded as harmful plants, or were the subjects of religious prohibition The broad bean, for example, was forbidden to the Egyptian priests, though later it was the cause of 'bean feasts' to a bean god Garlic, cabbage, asparagus and spinach have all had a somewhat chequered history The scarlet runner bean was long prevented from becoming a table delicacy by its value for ornamental purposes Tomatoes were first suspected of being poisonous, then became medicinal, and it was not until the 'eighties of last century that their nutritive value was realised in Great Britain. The potato survived a great volume of scorn, and was finally introduced to cultivation through sheer necessity—it mitigated the hardships of several famines. Mr. Bunyard suggests, somewhat whimsically, that lilies and tulips are edible, and appeals for an extension of "the Elizabethan spirit of adventure in the vegetable garden".

Sir Henry Wellcome, F.R.S.

THE President of the French Republic has paid a notable tribute to English medical and chemical research by conferring the honour of La Croix de Chevalier de la Légion d'Honneur upon Sir Henry Wellcome, who has also just been awarded the Remington medal of the American Pharmaceutical Association for distinguished service to pharmacy. Sir Henry is founder of the Wellcome Research Institution and head of Burroughs Wellcome and Co., London, manufacturers of fine chemicals and galenicals, with establishments in the United States, Italy, Canada, Australia, India, China, South Africa, the Argentine and other countries. Apart from the research and experimental laboratories of the establishments of Burroughs Wellcome and Co. which have carried out many original researches in pharmacy, Sir Henry Wellcome has established a number of scientific research laboratories and research museums which are co-ordinated under separate and distinct direction, such as the Wellcome Research Institution with its magnificent new building in Euston Road, London. In these associated chemical and medical research laboratories and museums, much original work has been done to throw light on abstruse problems in medicine and pharmacy and to settle hitherto uncertain points in the history of pharmacy.

Royal Irish Academy

AT the stated meeting on March 16 of the Royal Irish Academy, the following members were elected: Prof. K. G. Emeléus, professor of physics, Queen's University of Belfast; Prof. T. T. Flynn, professor of zoology, Queen's University of Belfast; Dr. R. H. Hunter, senior lecturer in anatomy, Queen's University of Belfast; Rev. J. Hynes, professor of archæology, University College, Galway; Rev. G. V. Jourdan, professor of ecclesiastical history, University of Dublin; Prof. M. F. Liddell, professor of German, University of Dublin; Mr. C. Blake Whelan, archæologist. The Abbé Victor Grégoire has been elected an honorary member in the Department of Science and Prof. Ellis H. Minns, Prof. Michael Rostovtzeff and Prof. Jean B. Vendryes honorary members in the Department of Polite Literature and Antiquities.

Announcements

THE first Royal Society soirée this year will be held in the Society's rooms at Burlington House on May 9 and the second on June 20.

PROF. A. M. CARR-SAUNDERS, Charles Booth professor of social science, University of Liverpool, has been elected a member of the Athenæum under the provisions of Rule II of the club, which empowers the annual election by the committee of a certain number of persons of distinguished eminence in science, literature, the arts or for public service.

PROF. H. LEVY, professor of mathematics at the Imperial College of Science, will deliver the twenty-fifth Conway Memorial Lecture on Wednesday, April 25, at 7 p.m. at Conway Hall, Red Lion Square, W.C.1, his subject being "Science in an Irrational Society". Admission will be free.

THE Academy of Sciences of the U.S.S.R. has elected the following to honorary membership of the Society: Sir Frederick Gowland Hopkins, Cambridge; Prof. G. H. Hardy, Cambridge; Dr. E. Schrödinger, Berlin (now Oxford); Prof. David Hilbert, Göttingen; Prof. Max Born, Göttingen (now Cambridge); Prof. T. Levi-Civita, Rome; and Prof. Carl Størmer, Oslo. Prof. Vaino Tanner, Helsingfors, has been elected a corresponding member.

THE Hillebrand Prize of the Chemical Society of Washington for the year 1933 has been awarded to the late Dr. Edward Wight Washburn for the discovery of the first practical method of separating the isotopes of hydrogen. He discovered the electrolytic method of separation, which has made possible the subsequent research into the properties of the isotopes of hydrogen, and has thus initiated almost a new era in chemistry, consequent upon the differences in the chemical and physical properties of these isotopes and their compounds.

THE Council of the Iron and Steel Institute announces that His Majesty the King has been graciously pleased to accept the Bessemer Gold Medal of the Institute for 1934. His Majesty has been the patron of the Iron and Steel Institute since his accession. The Bessemer Gold Medal was founded in 1873 by the late Sir (then Mr.) Henry Bessemer, the discoverer of the Bessemer process of steel-making and the second president of the Iron and Steel Institute. It has been awarded annually since that date to distinguished benefactors of the industry and particularly for pre-eminent contributions towards the scientific and technical knowledge of iron and steel. In 1899 Queen Victoria, and in 1906 King Edward VII, agreed to be recipients of this Medal.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A general manager for the Pigs Marketing Board—The Secretary, Pigs Marketing Board, Thames House, Millbank, London, S.W.1 (April 9). A public analyst for the Dorset County Council—The Clerk of the County Council, County Offices, Dorchester (April 18). A teacher of mathematics, and a teacher of applied mechanics and machine drawing, at the Junior Technical School, Sheffield—The Chief Education Officer, Leopold Street, Sheffield (April 19). A senior assistant librarian at University College, Hull—The Registrar (April 20). A temporary resident lecturer (woman) in history and geography at the Hereford Training College—The Principal.

Behaviour of Condensed Helium near Absolute Zero

THE recently published measurements[1] on some properties of condensed helium in conjunction with the facts known from the work of Keesom and his co workers[2] allow us to draw some conclusions on the behaviour of helium at very low temperatures

It has already been shown by Keesom who found the melting pressure to become nearly independent of temperature that the entropy difference between the two phases tends towards zero with falling temperature (Nernst s theorem)[3] This means that the liquid phase has to go into an ordered state[4] This change takes place at the λ point and is associated with a large loss of energy which though continuous occurs in a relatively small temperature range (One cannot say yet in which way this ordered state—called once by the author liquid degeneration —is realised Keesom[5] who recently published very similar considerations calls it a quasi crystalline state Clusius[6] also speaks of a crystalline state and adds the more specialised assumption of an association starting in the λ region)

Since the entropy difference vanishes the heat of fusion (ρ $T\Delta S = \Delta U + p\Delta V$) must tend towards zero *a fortiori*[7] This can be realised in two possible ways (1) both ΔU and $p\Delta V$ may become zero and this could scarcely be interpreted in any other way than that both phases become identical (The same would happen if the temperature coefficient of the melting pressure were not to disappear completely) (2) ΔU and $p\Delta V$ become equal but of opposite sign that is (*a*) ΔU or (*b*) ΔV changes its sign Our measurements now enable us to find both components of ρ and to extrapolate their values to absolute zero Although such an extrapolation entails some uncertainty we think it accurate enough to draw the following conclusions

One finds that along the melting curve the volume of the liquid remains always higher than that of the solid the volume difference even increases appreciably with falling temperature The energy of the liquid at 4° is greater than that of the solid just as with the normal liquid At about 2 5° however the energy difference begins to fall rapidly passes zero a little below 2° and approaches finally a value of about − 2 cal /gm atom This would mean that the possibility 2 (*a*) is realised

Thus the energy of the liquid at very low temperatures is smaller than that of the solid contrary to the normal Compressing the liquid to the solid one has to do work against the repulsive forces this work being greater than that done by the attractive forces Now arises the question of the origin of these strong repulsive forces for at the interatomic distances realised in liquid helium there can be no appreciable repulsion originating in the atomic fields every atom in the liquid having at its disposal a cube of 3 6 A length compared with the gas kinetic diameter of about 1 9 A

In order to understand this we have to consider the part played by the zero point energy Extrapolation of the measured latent heats of evaporation[8] to absolute zero gives an energy difference between the liquid without external pressure and the gas of about 14 cal From our data it then follows that the corresponding values for the liquid and the solid under the equilibrium pressure are 13 cal and 11 cal respectively Now the zero point energy of the solid under equilibrium pressure has a value of about 60 cal so that the lattice energy originating in the interatomic forces would amount to about 70 cal Thus we see that the zero point energy compensates by far the greater part of the lattice energy and therefore it must be the chief factor in the behaviour of the substance Having made a first estimate of the magnitude of the zero point energy from the deviations from Trouton s rule we have previously emphasised[9] that its large value probably is the explanation for helium remaining liquid The attractive forces cannot diminish the volume until they are compensated by the atomic repulsive forces the helium cannot crystallise with the normal volume but has to take up a bigger volume with corresponding smaller zero point energy[10] Only high external pressure can compress it into the close packed crystalline state

With diminishing volume the zero point energy must increase So on compressing one has to do work in order to increase the zero point energy and this is equivalent in many respects to the existence of a repulsive force At the interatomic distances realised in the liquid this greatly exceeds the repulsive forces resulting from the atomic fields and the most important factor in the compressibility is due to this

Before going into further details especially for explaining the negative coefficient of expansion below the λ point it seems necessary to have more specialised ideas on the structure of the liquid and to make assumptions for the way in which it passes into the ordered state It may be possible that the expansion coefficient will become normal again at lower temperatures and that the negative value in the λ region is of merely local character For this reason we will await the result of investigations at very low temperatures which are now in progress before going into further discussion

Wave Mechanics and Structural Chemistry

THE modern applications of wave mechanics to molecular structure and in particular the method of molecular orbitals developed by Mulliken and Lennard Jones have shown that it is not expedient to treat the individual links between atoms separately, and that the electrons in the molecule must be treated as a whole The organic chemist on the other hand, regards the molecule as held together by links from atom to atom, and the only distinction in kind which he recognises among links is into single, double and triple, and his method of representation is found to be capable of providing different formulæ for every experimentally distinct chemical substance, indeed it sometimes provides two formulæ for one substance, as with inseparable tautomers

If these views are both true, it follows that if a molecule with one structural formula can have (in the sense of the molecular orbital theory) more than one electronic constitution, these must be able to change into one another in less time than is required to isolate the substance, which involves a half life period of not more than a second or so, and a correspondingly minute heat of activation

Now on the theory of reaction proposed by London and Villars, and developed in detail by Eyring and Polanyi, the heat of activation of a chemical reaction is mainly the work needed to bring the atoms to those distances from one another which are required for their re grouping into the products of the reaction If this is so, an isomeric (tautomeric) reaction in which the atoms have nearly the same relative positions after as before, would have a very small heat of activation and would occur with great rapidity This seems to provide a reconciliation between the conclusions of wave mechanics and those of structural chemistry The atoms of a molecule may have one or more dispositions in space The number of these is the number of isomeric formulæ provided by the structural theory Only this number of forms can be isolated, because it is only between them that the rate of interconversion is slow Any finer modifications of the electron distribution which wave mechanics can detect must involve nearly the same positions of the atoms in space, and hence cannot lead to new isomers, as these would change into one another too rapidly We already know instances in which two structural formulæ give practically the same atomic positions, as in the Kekulé benzene formula, and then it is always found that the expected isomers are identical

It should be possible to define more precisely what is meant by nearly' the same positions We have evidence that the difference in length between a single and a double link, or in angle between the 109 5° of $\mathrm{X{-}X}\underset{\mathrm{X}}{\diagdown}$ and the 125° of $\mathrm{X{=}X}\underset{\mathrm{X}}{\diagdown}$ can be regarded as negligible from this point of view But we must expect a considerable range of differences corresponding to the wide range in rates of conversion, from those tautomers which can be separated at low temperatures to those which change into one another at a rate too great to be observed by any known method

Activities of Life and the Second Law of Thermodynamics

In a recent letter in Nature[1] Sir James Jeans, in replying to a criticism made by one of us[2], writes "Given perfectly level and frictionless railways, a man may move millions of tons of matter, and thereby decrease the entropy of the world enormously, without incurring any corresponding increase of entropy through the combustion of food or fuel" Not only can this surprising statement be disproved, but the very reverse of it can be readily demonstrated. The entropy decrease associated with the sorting out of trucks depends not on the number of tons but on the number of trucks Its magnitude would be the same if the trucks were replaced by an equal number of miniature trucks or counters or molecules If a man were to sort out a million trucks, the entropy decrease would be of the same order of magnitude (to within a few powers of ten) as the increase of entropy when he breathes a million molecules of oxygen To complete the proof of our assertion it is only necessary to estimate roughly how long it would take a man to sort out a million trucks and then estimate how many millions of millions of millions of millions of molecules of oxygen he must have breathed while he was doing it

The same letter contains the statement "We cannot, for example, suppose that the man who steers the *Mauretania* consumes food energy at a rate comparable with 100,000 h p more than normal" Indeed, no one with a knowledge of thermodynamics would suppose so The entropy associated with the steering of the *Mauretania* is of the order of magnitude of Boltzmann's constant k, simply because there is only one *Mauretania* being steered In thermodynamic parlance, the difference between the total energy and the free energy associated with the motion of the centre of mass of the *Mauretania* is of the order of magnitude kT where T is the absolute temperature, and this quantity is some 10^{30} times smaller than the kinetic energy of the ship The same thing may be expressed by saying that the Brownian movement of the *Mauretania* is negligible in comparison with its directed motion

In view of Sir James's lapse in thermodynamic reasoning we consider it not unreasonable to challenge his vague reference to orthodox physiology', and ask on what experimental evidence he relies for his statement concerning entropy changes in the brain

Induced Radioactivity of the Lighter Elements

We have been investigating the phenomenon of induced radioactivity in aluminium, boron and magnesium recently reported by Curie and Joliot[1], and have been able fully to confirm their observations, and also to add further details Using radium C′ α particles reduced in range to 6 1 cm, we find the relative yields of positrons during the entire decay from aluminium, boron and magnesium to be approximately 30, 10 and 7 Since the periods are respectively 3¼, 14 and 2½ minutes, the initial effects are in the ratio 6, 0 5, 2 With all materials we find an effect with a period of about 1 minute and of initial activity comparable with that of boron This must be due to some impurity which is always present, such as carbon, nitrogen or oxygen

Taking into account the solid angles involved, it appears that the probability of a 7×10^6 volt α particle producing a radiophosphorus atom by impact on aluminium is about 1 in 5×10^6 The above relative values are of no great significance, since the yield varies rapidly with the energy of the α particle in a manner dependent on the shape of the potential barrier which of course is different in these three elements This variation has been measured in the case of aluminium and we find that the yield of positrons increases by a factor of 15 as the energy of the α particle is changed from 5 5 to 7 × 10^6 volts

Using thorium C α particles the measurements have been extended to 8 3 × 10^6 volts and the probability of excitation appears to be reaching a maximum here This is in agreement with the far more detailed results obtained by investigating the protons liberated from aluminium by α particles Our results are compatible with the view that an α particle colliding with an aluminium nucleus has a certain chance of being captured and that from this arises a phenomenon analogous to radioactive branching the two alternatives being presumably the immediate emission of either a proton or a neutron It is the latter emission which produces the radioactive isotope of phosphorus which emits positrons The branching ratio appears to be of the order of 50 to 1 in favour of the proton emission

While we have been able to detect the positrons from aluminium by magnetic focusing the numbers were not sufficient to give definite measurements of the distribution with velocity but we detected positrons over the range 1 million to at least 2½ million volts Measurements of the absorption in copper and aluminium showed as the most significant feature an initial flat portion of the curve Comparing these curves with those obtained with the same apparatus but using β particles of thorium (C+C″) leads us to think that there are very few if any positrons of low energy Practically all of the positrons are stopped by 1 2 gm /cm ^{2} of aluminium which in the case of β particles would correspond to an energy of about 2½ million volts

An interesting feature of these absorption curves is that radiation is detectable through several millimetres of lead Part of this γ radiation is presumably the radiation arising from the annihilation of the positrons

A full report of these experiments will be published shortly

Inner Conversion in X Ray Spectra

IN a recent communication[1] Saha and Mukerjie have pointed out that although the transition $L_{\text{II,III}} \rightarrow L_{\text{I}}$ is not forbidden by quantum mechanics the X ray spectral line corresponding to it has never been observed and they have suggested that the failure to obtain such a line can be ascribed to its complete internal conversion in the *M*-shell Such an explanation would appear however to be inconsistent with the conclusions reached by Taylor and Mott[2] in their recent discussion of the nature of the internal conversion process for γ rays (Clearly the same considerations will apply to the internal conversion of X rays) Briefly stated in terms of the present problem the conclusion reached is as follows the presence of the *M* electrons increases the number of $L_{\text{III}} \rightarrow L_{\text{I}}$ transitions above that to be expected from a direct calculation of the electric moment corresponding to such a transition the rate of production of such induced transitions being only slightly less than the rate of ejection of the *M* electrons and thus the intensity of the observed X ray line should be only slightly decreased by the internal conversion

It is evident then that the phenomenon of the *internal conversion of X rays (Auger effect) can have* little bearing on the departure of measured X ray line intensities from those calculated theoretically and the statement that any radiation is completely converted in an inner shell is meaningless

That the above considerations are in fact important in these problems has become evident from a theoretical investigation one of us (E H S B) is making of the Auger effect full details of which will be published in due course While not yet complete this investigation is sufficiently advanced to show that allowing for the presence of induced transitions the *K* series internal conversion coefficient (defined as the ratio of the number of Auger electrons to the total number of transitions to the *K* shell occurring per unit time) is given closely by the expression $(1 + bZ^4)^{-1}$ Z being the atomic number of the element considered and b a constant characteristic of the particular transition A relation of this type satisfactorily fits the experimental data (as collected by Martin[3]) on the variation of the internal conversion coefficient with atomic number If however there were no induced transitions the internal conversion coefficient would be proportional to Z^{-4} and there would then arise for elements of low atomic number the paradox that the number of Auger electrons emitted per unit time exceeds the total number of transitions

Nuclear Moments of the Antimony Isotopes

Badami[1] first reported the existence of complex fine structures in the visible lines of the Sb II spectrum As a source he used a relatively high current arc (3–5 amp) and to explain the structures he suggested that the nuclear spin of the isotope 121 is 5/2 and that of the 123 isotope is 7/2 (These are the only isotopes in antimony)

I have succeeded in producing a very brilliant Sb II spectrum in a hollow cathode using only one seventh of an ampere and as a result the lines are so very much sharper than those in the arc that the extremely complex patterns encountered are more completely resolved many lines showing more components than those reported by Badami The analysis of the line patterns shows without any doubt that the nuclear mechanical spins of both 121 and 123 are 5/2 but that the two isotopes have different nuclear magnetic moments in the ratio 1 36 1 the 121 isotope having the larger value This may be compared with the ratio 1 27 1 in gallium the only other known case which has two isotopes with identical spins (½) and different nuclear magnetic moments

The following comparison of the structure given by Badami and by me for the line λ 5639 7 ($6s$ ${}^3P_2 - 6p$ ${}^3S_1$) shows to what extent the hollow cathode patterns are more clearly resolved

Badami	0 (6)		205 (5)			450 (4)	584 (4)	760 (1)	cm	$\times 10^{-3}$
Tolansky	0 (10)	71 (8)	217 (9)	319 (3)	399 (3½)	477 (6)	606 (5)	728 (1½)	cm	$\times 10^{-3}$

It is seen that Badami s values are those which would arise from the blending of components due to excessive line width

Full details with analysis will be communicated elsewhere shortly

The Neutrino

This view has recently been put forward[1] that a neutral particle of about electronic mass and spin $\frac{1}{2}\hbar$ (where $\hbar = h/2\pi$) exists and that this neutrino is emitted together with an electron in β-decay This assumption allows the conservation laws for energy and angular momentum to hold in nuclear physics[2] Both the emitted electron and neutrino could be described either (*a*) as having existed before in the nucleus or (*b*) as being created at the time of emission In a recent paper[3] Fermi has proposed a model of β disintegration using (*b*) which seems to be confirmed by experiment

According to (*a*) one should picture the neutron as being built up of a proton an electron and a neutrino while if one accepts (*b*) the rôles of neutron and proton would be symmetrical[4] and one would expect that positive electrons could also sometimes be created together with a neutrino in nuclear transformations Therefore the experiments of Curie and Joliot[5] on an artificial positive β decay give strong support to method (*b*) as one can scarcely assume the existence of positive electrons in the nucleus

Why then have positive electrons never been found in the natural β-decay ? This can be explained by the fact that radioactivity usually starts with α-emission and therefore leads to nuclei the charge of which is too small compared with their weight The artificial β emission was found for two unstable nuclei (most probably N^{13} and P^{30}) formed by capture of an α particle and emission of a neutron and therefore having too high a charge for their mass

A consequence of assumption (*b*) is that two isobares differing by 1 in atomic number can only be stable if the difference of their masses is less than the mass of electron and neutrino together For otherwise the heavier of the two elements would disintegrate with emission of a neutrino and either a positive or negative electron There will be only a limited region on the mass defect curve probably at medium atomic weight where such small differences are possible In fact neighbouring isobares have only been found with the mass numbers 87 115 121 123 (187) (203) while isobares with atomic numbers differing by 2 are very frequent In the first case one of the two nuclei (Rb) is known to emit β rays In each of the last two cases one of the two isobares is stated to be exceedingly rare and its identification might be due to experimental error The other three cases actually lie close together and have medium weight A particular case of isobares are proton and neutron Since all experimentally deduced values of the neutron mass lie between 1 0068 and 1 0078 they are certainly both stable even if the mass of the neutrino should be zero

The possibility of creating neutrinos necessarily implies the existence of annihilation processes The most interesting amongst them would be the following a neutrino hits a nucleus and a positive or negative electron is created while the neutrino disappears and the charge of the nucleus changes by 1

The cross section σ for such processes for a neutrino of given energy may be estimated from the lifetime *t* of β radiating nuclei giving neutrinos of the same energy (This estimate is in accord with Fermi s model but is more general) Dimensionally the connexion will be

$$\sigma \quad A/t$$

where *A* has the dimension cm^2 sec The longest length and time which can possibly be involved are $\hbar/mc$ and $\hbar/mc^2$ Therefore

$$\sigma < \frac{\hbar^3}{m^3c^4t}$$

For an energy of $2\ 3 \times 10^6$ volts *t* is 3 minutes and therefore $\sigma < 10^{-44}\ \text{cm}^2$ (corresponding to a penetrating power of 10^{16} km in solid matter) It is therefore absolutely impossible to observe processes of this kind with the neutrinos created in nuclear transformations

With increasing energy σ increases (in Fermi s model[3] for large energies as $(E/mc^2)^2$) but even if one assumes a very steep increase it seems highly improbable that even for cosmic ray energies σ becomes large enough to allow the process to be observed

If therefore the neutrino has no interaction with other particles besides the processes of creation and annihilation mentioned—and it is not necessary to assume interaction in order to explain the function of the neutrino in nuclear transformations—one can conclude that there is no practically possible way of observing the neutrino

Changes in the Lipolytic Activity of Different Organs during Tuberculosis

In continuation of our earlier work on lipases[1] we have followed the changes in the lipase content of different organs of guinea pigs infected with bovine tuberculosis Lipase determinations were made from liver pancreas lungs and blood serum using tributyrine as substrate It appeared that, coincident with the development of tuberculosis the lipolytic activity of liver pancreas and of blood serum is considerably lowered The results are given in the following table

Lipase Content (Titrated Lipase Units) per 1 gm of Fresh Material

	Liver	Pancreas	Lungs	Serum
Infected guinea pigs	396 (117–566)	425 (191 783)	85 (48–130)	28 (22–36)
Controls	1140 (898–1410)	832 (488–1391)	85 (46–107)	40 (34 46)

Each group consisted of five animals The infected animals were killed 2 10 days before the expected natural death The figures in brackets indicate the variations in respective series

In certain series when the bacterial strain used did not produce general tuberculosis the lipase contents of liver and pancreas were not lowered a decrease being noted only in blood serum

The cause of the decrease of lipolytic activity of different organs during tuberculosis is still problematic It might be assumed that the destructive action of the tubercle bacilli on the tissues also destroys the lipases This assumption is supported by our observation that in the sound portions of liver the lipase content is considerably higher than in the portions infected by tuberculosis

The Third Vitamin D

A SHORT time ago[1] we reported that vitamin D found in ether extract of meadow hay had the same properties as described by Kon and Booth[2] for vitamin D in butter in that only one fifth of this vitamin after saponification is again found in the unsaponifiable fraction We have since examined butter and have been able to confirm Kon and Booth s results as regards its vitamin D content We considered it of interest to investigate whether the missing four fifths of the anti rachitic vitamin might possibly be found in the saponifiable fraction of the ether extract of butter or hay For this purpose a small excess of acetic acid was added and the free fatty acids taken up with ether and isolated It was then found that the missing four fifths of the original vitamin D were among the free fatty acids Thus with alkali it gives a water soluble substance deprived of alkali it is again soluble in ether

As certain difficulties were involved in giving daily doses of natural butter we tried to concentrate vitamin D in butter by shaking with a similar quantity of warm ethyl alcohol the melted butter fat which had been dried with sodium sulphate[3] [4] It proved that four per cent of the butter fat dissolved in the alcohol This four per cent had an anti rachitic strength 15 times as great as natural butter inasmuch as it was active in curative daily doses of 20 mgm as shown by Poulsson and Løvenskiold s method[5] The product which was obtained was twice saponified and yielded 11 09 per cent unsaponifiable matter Of this unsaponifiable matter it was necessary to give daily doses equivalent to 100 mgm of the original extract in order to obtain an anti rachitic result corresponding to 20 mgm of this Of the isolated free fatty acids 25 mgm per day produced the same effect as 20 mgm of the initial material Thus it will be seen that about a fifth of the anti rachitic vitamin has accompanied the unsaponifiable matter and about four fifths the saponifiable fraction We obtained a similar result with ether extract of meadow hay Here the daily doses of the hay powder extract were 4 mgm Of the unsaponifiable matter they corresponded to 20 mgm and of the fatty acids to 5 mgm

It was of interest to investigate whether the vitamin D from cow s liver behaved similarly Ether extract of cow s liver showed a suitable anti rachitic effect in daily doses of 40 mgm The unsaponifiable matter showed a corresponding effect in daily doses equivalent to 200 mgm and the free fatty acids had a similar effect in daily doses of 60 mgm In other words vitamin D in extract of hay cow s liver and butter has the same properties With ether extract of the human liver two thirds of the vitamin D is in the unsaponifiable matter and only one third among the free fatty acids These conditions vary somewhat in the human being in the individual cases a circumstance which is probably accounted for by the fact that the human being obtains sustenance from the products of both land and sea and thus has a stock of the various D vitamins

Effect of a Meteoric Shower on the Ionosphere

OF the various agencies responsible for producing and maintaining ionisation of the ionosphere bombardment of the upper atmosphere by meteors has been suggested as one Skellett[1] has carried out a calculation of the energy received by the earth due to impact of the meteors and finds that during a meteoric shower it might be so high as a fourteenth of that due to ultra violet light from the sun He therefore concludes that meteoric showers might be one of the factors disturbing the ionisation of the upper atmosphere In order to find if any correlation exists between the occurrence of the two phenomena Schafer and Goodall[2] measured the height of the *E* region during the Leonid meteoric shower of 1931 They found that on some nights the ionic density attained high values Unfortunately their observations were vitiated by a magnetic storm which was in progress at that time Though they were unable to draw any definite conclusion regarding the correlation they summarise their observations by saying that there is reason to believe that the presence of meteors in unusual numbers can cause increased ionisation of an intermittent nature in the region of the lower layer

Considering the importance of the subject we thought it worth while to take records of the ionisation content of the *E* layer during the Leonid shower of 1933 The method employed was the well known one developed by Appleton[3] and consisted in determining the frequency at which upwardly directed radio waves pierced the region under investi gation Fig 1 depicts the results of our observations carried out on the nights of November 13, 14 and 17, 1933, between the hours 2300 and 0700 It will be noticed that on the nights of November 13 and 14 the equivalent electron densities attained values of $3\ 3 \times 10^6$ and $2\ 2 \times 10^6$ respectively The penetration frequencies for these ionic densities correspond to wave lengths of 87 and 71 4 metres

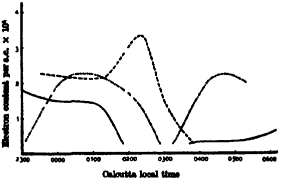

FIG 1 Electron content of the *E* layer during the 1933 Leonid shower
---- Nov 13 - - Nov 14 —— Nov 17

Such high densities are remarkable, because in the course of our fortnightly observations during the Polar Year 1932–33, we never recorded such densities In fact we were never able to obtain echoes on 75 metres for our midnight observations The high ionic density recorded, therefore, strongly suggests that the effect was due to the impact of meteors on the upper atmosphere It should be mentioned that records kept at the Magnetic Observatory, Colaba Bombay, and the Solar Observatory, Kodaikanal, Madras, show that no marked magnetic disturbance or solar activities occurred on these days

Terminal and Initial Parenchyma in Wood

MR K A CHOWDHURY's remarks upon the position of the parenchyma in *Terminalia tomentosa*[1] would seem to be applicable to other woods also A recent examination of the wood of *Cedrela odorata* in this laboratory showed that the larger vessels of the early wood are partly embedded in parenchyma, some of which, judged by its position, was laid down rather earlier than these vessels It is possible that the latest wood of a season's growth consists chiefly of parenchyma, and that the early wood of the following season is similarly constituted, but the parenchyma is sufficiently homogeneous to render this possibility improbable Another specimen of *Cedrela*, probably *C odorata*, showed that the parenchyma separated a region of rather small, fairly thick walled fibres from another of larger, relatively thin-walled fibres, the comparatively large size and thin walls of the cells of the parenchyma in both these specimens suggest that it was laid down at the beginning of a season's growth, not at the end; it is desirable to confirm this by studies on the living tree

Several other Meliaceous woods were examined, but with less conclusive results In *Swietenia Mahagoni*, the parenchyma appears to be terminal and not initial, and in this wood the parenchyma cells are rather small, with relatively thick walls, which would seem to confirm the view that they are laid down at the end of the growing season In *Khaya grandis* and *Carapa guianensis*, it was not possible to decide if the parenchyma was terminal or initial

It is well known that the vessels of the pore ring in teak (*Tectona grandis*) may be associated with parenchyma, and it would seem to be justifiable to refer to this as initial parenchyma

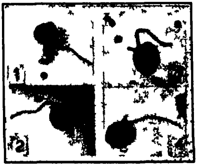
Zoospore Ciliation in the Plasmodiophorales

ZOOSPORES of *Plasmodiophora brassicae*, Woron and *Spongospora subterranea* (Wallroth) Lagerheim have been described in the literature as uniciliate Examination of active zoospores would appear to substantiate this description However, when preparations stained by Cotner's[1] method are used, it can be shown that in addition to the long cilium, so apparent in the living zoospore, there is another which is shorter and less conspicuous This biciliate character is illustrated by photomicrographs of zoo spores of *P brassicae* (Figs 1 and 2) and *S subterranea* (Figs 3 and 4)



Great numbers of such zoospores were obtained by germinating, in dilute inorganic nutrient solutions, resting spores which had previously been wet, frozen and dried several times In size and manner of swimming, these zoospores fit the descriptions given by other writers

Research Items

Lower Palæolithic 'Cleavers', Northern Nigeria Mr Henry Balfour in *Man* for February comments on the occurrence of the so called cleaver of lower palæolithic facies in Nigeria The implement is of axe like type characterised mainly by having the cutting edge formed by the intersection of two large flake scars one on either side of the surface of the implement The junction of the two scars along the lower margin affords a very sharp cutting edge which however does not stand prolonged hard usage Until recent years this type has received scant recognition since it had been noted as an occasional occurrence only among Chelleo Acheulean implements and was considered to be somewhat rare In South Africa it must be accorded the status of a dominant type in view of its abundance and wide distribution south of the Zambezi Its further dispersal in Africa is a matter of importance and its occurrence in northern Nigeria where it had not previously been recorded is to be noted Well defined examples are included in a collection of implements of lower palæolithic facies which is housed in the Government Offices at Jos on the Bauchi Plateau These were discovered largely in the course of tin mining operations Two examples of which sketches were made by the author are figured Of these one is about 16 cm long by 8 7 cm in maximum width and consists of a massive flake The greater area of one surface is the untouched scar of detachment the other surface exhibits a large area of coarse flaking The second is larger and better worked possibly of diorite 17 5 cm long by nearly 11 cm wide It is considerably weathered and patinated The form is more symmetrical and the flaking less coarse than in the first specimen but the technique is similar in the two instances There can be no doubt that the cleavers of West and South Africa are closely related morphologically

Tuamotuan Religion The religious beliefs of the natives of Tuamotu archipelago which extends for more than 600 miles from north west to south east between the Society Islands and the Marquesas are studied by Mr J Frank Stimson in *Bulletins* 103 and 111 of the Bernice P Bishop Museum Honolulu Few natives are now acquainted with the pre Christian beliefs but the difficulties of study are further increased by the fact that there would appear to have been two forms of belief an esoteric belief the cult of a supreme god Kiho knowledge of which was confined to priests and nobles and an exoteric cult for the ordinary people in which the name of the supreme deity was concealed or disguised This esoteric knowledge in the form of chants or cosmogonic descriptive and genealogical material was handed down from generation to generation but owing to a confusion with the powers of evil in early missionary days it came to be looked upon as suspect and has now almost vanished The philosophic ideas of the chants of which a series is recorded in *Bulletin* 111 were of an extremely high order Study of the distribution of this cult of which traces are to be found in various parts of Polynesia suggests that it was introduced into the Pacific by an early wave of Polynesians termed for convenience palæ Polynesian, the ideas it embodied possibly being derived from an ancient civilisation in south eastern Asia These palæ Polynesians carried the cult to Tahiti and thence in successive migrations to the marginal confines of Polynesia A later Polynesian wave which may be designated neo Polynesian developed a religious system emphasising the creative rather than the tree type of cosmogenesis wherein Tangaroa was viewed as the supreme creator The exoteric version of the cult posited a group of secondary gods whose attributes were suited to the beliefs of the people and served them as objects of worship and as tutelary deities

Land Snakes of Hong Kong Twenty nine species of land snakes belonging to twenty genera have been recorded from Hong Kong Territories and a key to the genera and some species has been compiled by G A C Herklots (*Hong Kong Naturalist* 4 113 Dec 1933) Of the twenty nine species no fewer than six are venomous and two of these are described and portrayed in colour—the common krait (*Bungarus multicinctus*) and the banded krait (*B fasciatus*) The bite of the latter is fatal to fowls and dogs but apparently not to man On the other hand the virulence of the common krait is about twice that of the cobra and twenty eight times that of the banded krait an account is repeated of the deaths of three men successively bitten by the Indian race of common krait while a fourth recovered after being seriously ill

Invertebrates from the Vanderbilt Museum A fourth volume of the reports on the collections made by Mr William K Vanderbilt on a series of cruises conducted in his yachts *Eagle* and *Ara* has now been published adding Cœlenterata Echinodermata and Mollusca to those on fishes and Crustacea (*Bull Vanderbilt Marine Museum* vol 4 Scientific Results of Cruises of the Yachts *Eagle* and *Ara* 1921 1928 William K Vanderbilt Commanding Cœlenterata Echinodermata and Mollusca By Lee Boone Huntington Long Island N Y) Four faunal regions are involved in these expeditions the West Indian region, the Labrador New England region the tropical American Pacific and the Mediterranean The depths dredged varied from quite shallow water to 900 fathoms besides littoral collections Notes from colour sketches made by Mr Vanderbilt on the spot are added The specimens are chiefly known species but one new coral is described *Corallum vanderbilti* from Cuba dredged by the *Ara* below 100 fathoms One colony of *Stenogorgia casta* Verrill hitherto only known from the type locality taken by the *Blake* was found off the Alligator Reef Florida and is many times larger than the type There is a magnificent collection of echinoderms with many details of spines and pedicellariæ well figured but perhaps the most interesting find was a mother octopus *Octopus vulgaris* about 10 in across the umbrella guarding her young the brood numbering 522 seven of which had not fully escaped from the egg capsule This was taken from a loggerhead sponge Knight s Key Florida dredging at 2 fathoms A female octopus may lay up to 1 000 eggs in a brood all connected by a thin flexible rope fastened in some rock crevice The mother tends them, blowing water on them through her funnel, cleaning and aerating them This is probably the first capture of an entire brood An egg laden female *Argonauta argo* with about 500 eggs in the shell was dredged from 300 fathoms from off Cape Mala, Panama

Larval Decapods from Madras. Mr M Krishna Menon describes some very interesting larvæ in his paper "The Life Histories of Decapod Crustacea from Madras" (*Bull Madras Gov Mus* New Series Natural History Section, Vol 3 No 3 1933) There are many decapod larvæ in the Madras plankton in the period immediately following the monsoons, the end of November and the four following months Not only do we know little about the life histories of the decapods from this particular region, but we also know little of those from almost any region, and any detailed investigation of this kind is valuable The animals chosen are *Acetes erythraeus* in the family Sergestidæ a *Callianassa* and (probably) a *Upogebia* species unknown, and *Hippa asiatica* Unfortunately it was not possible to hatch the eggs in the laboratory, but it was found that late larvæ could often be kept until they metamorphosed and the genus or species ascertained A complete account of the development of *Acetes* is given for the first time, for the larvæ are very common in the Madras plankton eight larval stages being described Both the Callianassa and Upogebiid are interesting and present unusual features the first having an abbreviated development showing certain affinities with *Axius*, the second having some unique features among the Upogebiinæ The adult of this last larva has not been obtained

Tropical Pacific Foraminifera In his paper The Foraminifera of the Tropical Pacific Collections of the *Albatross*, 1899–1900" (Part 2, Lagenidæ to Alveolinellidæ, United States National Museum Bull 161, 1933) J A Cushman continues to describe and illustrate the Foraminifera of the tropical Pacific collected by the United States Bureau of Fisheries steamer *Albatross* together with certain other related material from shallow water of the same region From the study of the shallow water Foraminifera living in the various oceanic islands, it has become evident that many species are very localised in their distribution, and probably a careful survey of the different island groups will show that there are many of these isolated species or varieties that have not yet been recognised When these occur, they are often to be found in great numbers, as is frequently the case with such localised species in other groups The genus *Lagena* is the largest of those recorded, with no less than 29 species and several varieties The author states that there is scarcely any other group of Foraminifera in which so much is needed in the way of detailed studies in regard to structure and variation Many of the species seem to be very widely distributed while others have very definite ranges He includes *Entosolenia* with *Lagena* although fully realising the distinction between them, leaving the complete study of this important group for future workers The paper is illustrated with 19 excellent photographic plates

Australian *Casuarinas* A short article in the *Argus* of Melbourne, Australia, dated March 4, 1933, gives a very interesting description of several commercially useful species of the genus *Casuarina* ("Australian Oaks, their Economic Value" by J. W. Audas) Australian species of *Casuarina* or 'sheoaks' are evergreen and grow rapidly, have long life, are free from diseases and pests, have wood which is of high quality for cabinet making and is resistant to the effects of weather, and even the bark is of medicinal value The trees will grow on the poorest of soils, and the young sprouts provide food for cattle To this end they are often pollarded Loose sandy soils may be stabilised by growing species of *Casuarina* upon them The economic characteristics of *Casuarina suberosa* (black sheoak), *C stricta* (drooping sheoak), *C Luehmannii* (buloke) and *C glauca* (grey buloke) are given, and a plea for their extended cultivation is made

Genetics of Poppies A genetical investigation of the poppies has been made by Dr J Philp (*J Genetics*, 28, No 2) In *Papaver Rhœas* which shows some self sterility, the inheritance of eight factors for flower colour has been investigated For seven of these factors 91 of the 128 possible phenotypes have been recognised These factors are found to fall into three linkage groups There appear to be two factors for hair colour, one of which is linked with two of the factors for petal colour Doubleness is incompletely recessive to singleness and is probably controlled by several factors Latex colour is also apparently determined by two factors and is affected by the factor p for flower colour The phenomena of segregation and crossing over are the same for the male and female sides The species is very heterozygous, while *P commutatum*, which has a narrower distribution, is very homozygous, indicating that the natural selection of types has been more intense or that mutations have occurred less freely This may perhaps explain the general dominance or epistasy of its characters over those of *P rhœas* The two species are regarded as recently differentiated from a common origin and both have $2n - 14$ chromosomes

Crustal Blocks in the Kwanto District In an earlier memoir (see NATURE, 129, 321, 1932), Prof N Miyabe showed that, in the Boso peninsula, the earth's crust consists of many blocks that have been tilted in various directions He has now applied the same methods to the south west Kwanto district (*Bull Earthq Res Inst*, 11, 639 692, 1933), using the vertical displacements of nearly 500 secondary and tertiary triangulation points during the interval 1892–1925 In this way, he has drawn the boundaries of 73 blocks the horizontal dimensions of which are about 10 km, and has determined the magnitudes and directions of their tilts Some of them may consist of several secondary blocks, each 2–3 km across Both the tilting and the vertical displacement of the blocks are, as a rule, greater to the west, than to the east, of the River Sagami Near Ooiso, one block was elevated 127 6 cm, while closely adjoining blocks to the north west were lowered by 67 9 and 77 5 cm Several of the boundaries of the blocks agree fairly well with known tectonic lines For example, the Tanna fault, along which displacements occurred with the earthquake of November 26, 1930, coincides nearly with the eastern boundary of a block in the Idu peninsula

Population Map of England. A map showing the density of population of England and Wales at the census of 1931 has been published by the Ordnance Survey (1*s* 6*d*, flat and unmounted) This completes the map of Great Britain, of which the Scottish sheet was published last year The scale is 1 to 1,000,000 Density of population is shown by deepening tints of brown, olive green and black, which merge as satisfactorily as tints can be expected to do There are twelve tints ranging from occasional" population of 0–1 per square mile to very congested" of 76,800 or more per square mile There are inset maps of the County of London (scale 4 miles to an inch) and county boundaries Names on the main map are those of towns, certain physical features and in blue, rivers and lakes Index letters and numbers in the margin facilitate reference The sheet overlaps the previously published one from northern Yorkshire to the Firth of Forth A one sheet edition of the combined sheets is also published

Rainfall in Netherlands Indies Dr J Boerema has extended his statistical study of the rainfall of the Netherlands Indies (*Kon Mag Met Observ Batavia* No 26) This is the fourth volume dealing with this subject and consists entirely of rainfall maps for Celebes on a scale of one to three million The maps give a picture of the average annual rainfall and also the average rainfall for each individual month by means of isohyets, the zones of different intensities bounded by the various isohyets are brought into prominence by a scale of shading and the use of blue tint for the heavier falls The interval between successive isohyets has to be large as Celebes lies in the tropical rain belt (the equator passes through the northern part of the island) and it is only in October that the blue tint (rainfall more than 300 mm that is than about 12 in) does not appear anywhere on the map The interval on the annual map is 500 mm except for the wettest regions where it changes to 1 000 mm and on the monthly maps is 50 mm for the dry regions and 100 mm for the wet The presentation of the rainfall in this form, although very good for most purposes is not very suitable for a comparative study of the seasonal variation of rainfall in different parts of the island They show however that the seasonal variation is far from following a similar course throughout the island

Progressive Lightning Schonland and Collens (*Proc Roy Soc*, A, Feb) have photographed a number of South African lightning flashes using a camera invented by Boys in which two lenses are mounted at opposite ends of a diameter of a circle and rotated at high speed about the centre of the circle Successive parts of a discharge are thus drawn out along a circular track By comparing the pictures produced by the two lenses moving in opposite directions, the nature of a flash may be elucidated The measurements show that in many cases the first stroke of a flash consists of a bright dart moving from cloud to earth with a velocity of the order 8×10^8 cm per sec The bright dart is of the order 50 metres long, and probably consists of an avalanche of electrons The evidence is that the flashes which show leader strokes are such that the base of the cloud is the cathode of the discharge and that a dart of electrons can be propagated at the velocities observed The strokes which follow the leader spread from the ground upwards, with higher velocities of the order 10^{10} cm per sec These strokes resemble flames rather than darts and it is suggested that the ionisation is thermal in character In some cases these main strokes branched upwards, the branches developing after the main discharge had developed at the branching point (see also NATURE, 132 407, Sept 9 1933)

Photochemical Union of Hydrogen and Chlorine Bateman and Allmand (*J Chem Soc* 157, 1933) describe some experiments on the effect of light of varying wave length on the photochemical union of a mixture of pure hydrogen and chlorine, which did not exhibit any induction period when confined over water Insolation was effected by either a quartz mercury lamp or a tungsten filament lamp in conjunction with a large aperture quartz monochromator The results correct some previously reported (cf NATURE 131, 656 May 6 1933) It was found that the rate of photochemical union in monochromatic light of wave length 313 mμ was proportional to the intensity and that the quantum yield was independent of wave length between 400 and 490 mμ The quantum yield remained of the same order also from 400 mμ to 290 mμ but appeared to fall off by 10 20 per cent when passing from the visible to the ultra violet region It also fell off when passing from 490 mμ to longer wave lengths It had previously been shown that the reaction was definitely sensitive to light of 546 mμ (the green mercury line) and in the present experiments a definite reaction was found in the region 540 550 mμ With monochromatic mercury lamp radiation of 492 mμ anomalous results were found This wave length lies just beyond the convergence limit 478 5 mμ of the chlorine banded spectrum The relative quantum efficiencies were found to be low at first but progressively increased from values below 1 to a constant value of 8 Interposition of dark periods during the increasing range caused a fall on re illumination but had no effect when the value 8 had been attained No anomaly *in this region was found with the continuous light* source

Heavy Water The *Journal of the American Chemical Society* of February contains several communications on heavy water and heavy hydrogen Gilfillan examined the density of water obtained by distillation of sea water, both that taken from a depth and that from the surface In both cases an excess of density above the normal was found Different samples of sea water gave the same specific gravity whilst tap water purified in the same way gave a different value the specific gravity of the distillate from sea water being 1 0000023 at 0 when water from tap water is taken as unity Halford Anderson and Bates find that transfer of heavy hydrogen from water to acetone occurs on warming the two liquids together in presence of potassium carbonate Davis and Johnston find a separation of hydrogen isotopes when water is treated with sodium G N Lewis and Schutz describe the properties of acetic acid containing the heavy isotope of hydrogen This acid melted 3 3° below ordinary acetic acid and shows a higher vapour pressure, because of the higher association in the vapour phase The heavy isotope was in the carboxyl hydrogen and no interchange with the hydrogen in the methyl group occurs on treatment Lewis, Macdonald and Schutz have prepared hydrochloric acid with the heavy isotope and measured the vapour pressures of the liquid and solid forms The results give $\log_{10}p_1/p_2 - 15\ 4/T - 0\ 075$ for the liquids and $\log_{10}p_1/p_2 = -57\ 7/T + 0\ 387$ for the solids The ratio of the vapour pressures reaches a maximum of 1 05 at the triple point, below which they approach each other as the temperature is lowered The calculated heat of fusion is very low

Outlying Museums of the Empire*

THE great survey of the museums of the Empire conceived by Sir Henry Miers and S F Markham has now been completed by them with the assistance of Dr F A Bather, T Sheppard and others The final reports on the museums in scattered outliers of the British Empire bring to a close a series of surveys which has reviewed more than a thousand museums and art galleries For the accomplishment and success of these surveys as well as to the surveyors credit must be awarded to the Carnegie Corporation of New York which financed the inquiries and to the Museums Association which acted as general headquarters and under the name of which the reports have been published Along with the reports proper (bound in paper covers) there are issued (bound in cloth as if for much service) a directory of the museums in Australia and New Zealand and another of those in the scattered islands of the Empire compilations the merit of which makes it certain that from this starting point the progress of these museums will be measured

The condition of the isolated and island museums is the most unsatisfactory revealed by the Empire Survey The reason may be possibly historic possibly psychological but whatever the cause all observers agree that the islands of the British Empire present one of the most difficult problems in the realm of cultural services Yet from the reports it is clear and one s own knowledge of their publications confirms that in places excellent scientific work has been done as in the Raffles Museum at Singapore or the Sarawak Museum at Kuching But in most places valuable scientific material is disappearing with little attempt at collection and conservation simply because finances are inadequate Exhibited collections suffer from the same inadequacies of money and staff though the fact that in several of the places illiterate natives form (as in Colombo) an overwhelming proportion of the museum visitors, must tend to discourage the utmost effort at arrangement since neither English nor vernacular labels are understood Yet these natives get pleasure and interest from the exhibits themselves

Many of the remarks in the report on Australia and New Zealand apply to both countries and indeed to other Dominions Both have been severely hit by the depression and the staffs of their museums have not kept pace with their growth or have been actually reduced with the inevitable deterioration Over and over again it is insisted that the chief need of a museum is a competent and keen curator who deserves an adequate salary We read of one of the oldest and most important museums being run by a director and a taxidermist and of university trained botanists and entomologists receiving less than £3 a week Buildings are often inadequate and liable to destruction by fire In these circumstances the good work already accomplished generally by private or municipal effort (more marked in New Zealand than in Australia) is to be warmly commended

Writing for the Carnegie Corporation the authors naturally emphasise the exhibition and educational side of museum work and occasionally seem merely to tolerate the researches made known by the museums in many excellent publications No doubt they themselves actually realise that in a new country being changed by civilisation the first duty of a museum is conservation and that research must precede exposition Governing authorities however are slow to realise the help that museums might give to education to general culture and to the severely practical work of life

The advantages of co operation are insisted on and here the Museums Association can extend its good work Recently it has brought into being a strong Empire Committee on which representatives of the Home Government and of the Dominions meet those who have conducted the surveys in order to administer to best advantage the funds allotted by the Carnegie Corporation But loans exchanges, and the pooling of information are no less important The Dominions desire much from the Homeland but is it not ridiculous that type specimens of British Jurassic plants and shells should as the Directory tells us be in an Antipodean museum ?

The Roll call of the Hydrogens (Hydranes)

By Prof Henry E Armstrong, F R S

1 THE task of naming the homologues of hydrogen is not to be undertaken lightly Nomenclature is of such importance that all considerations should be laid aside except those of reasoned expediency and sound philological practice The example set by Faraday just a century ago in framing names for use in describing and discussing electrochemical phenomena may well serve us to day His words have stood the test of time because of the extreme care with which they were chosen

2 The new gases (from water) are clearly all *Hydrogens* (Water stuffs) as each has its own water in water They are to be grouped under their *Atomic Number* 1 as homologous members of the first term in the periodic series of elements It would seem to be desirable to have an index name common to all members of the group *Deuterium* is in no way reminiscent of water and also has no particular group significance Second to what ? is the question that at once arises The name would be a fit one for the first member of the second group (*Atomic Number* 2) in the periodic series If we could agree so to use it succeeding groups might well have similarly significant group names—*Triterium* *Tetraterium* etc up to 92 in addition to the familiar names

3 Members of the first group are logically all to be regarded and represented as *Hydrogens* in the same way that members of the C_nH_{2n+2} series of saturated hydrocarbons are all included under the group name

Paraffins or Methanes (*Ethanes*) The individual names of these all have the same ending and are also significant of composition, as a series of numerical indices are prefixed to a single terminal The principle thus followed in naming homologous paraffins may well be followed in naming hydrogens One of the happiest suggestions ever made was Hofmann's, that the terminal *ane* should be applied to all paraffins In the chemist's mind *ane* is now always associated with an initial series Hofmann took the second great step in systematic nomenclature, the first being that taken by Lavoisier and his colleagues Methyl, ethyl and propyl being well established, good names, he preserved these and began numbering at the fourth term, tetrane

4 Applying the Hofmann principle to the hydrogens we have the names

Hydrogen, Deuthydrogen, Trithydrogen

Maybe it will be found that the series ends here and that further addition of a proton gives rise to a complex which swallows its own tail, producing helium Helium may not be like a whale but it is very like the closed complex benzene Earthly chemists may be forgiven if they go so far as to imagine that not a few elements may come to be regarded as polyhelides, just as a large proportion of hydrocarbons are polybenzenes It is permissible to be prophetic even at a christening party Lord Rutherford would seem to forecast the possibility of a *prohelium*, in the second group, of weight 3—an elemental trimethylene

5 Hydrogen, however, is not a name that is universally used At least an alias, of a more general character, may be desirable In all humility, I suggest the simple term *hydrane* The analogy with methane will be obvious —

	Alternative symbols		
Hydrane	H	H^{α}	H
Deuthydrane	HH	H^{β}	H^{2}
Trithydrane	HHH	H^{γ}	H^{3}

With reference to the special symbols here introduced, we represent paraffins by complex structural formulæ, by special symbols such as CH_3 CH_3, why not hydranes ? Recent observations (NATURE, Feb 17) seem to indicate peculiarities in behaviour which justify, if they do not demand, the use of peculiar symbols

6 Compounds might be named systematically as follows

Hydranol	(Hydrol)	H O H
Hydranone	(Hydrone)	
Deuthydranone	(deuthydrone)	HH O HH
Hemideuthydranone	(hydrone)	H O HH
Hydranamine	(hydramine)	NH_3
Deuthydranamine	(deuthydramine)	NH_2.HH
Di ,,	,,	NH HH_2
Tri ,,	,,	N.HH_3
Deuthydranomethane		CH_3 HH
Dideuthydranomethane		CH_2 HH_2
Tri ,,	,,	CH HH_3
Tetra ,,	,,	C HH_4

7 If proton be the name given to the elemental unit H, the corresponding deuthydrogen or deuthydrane unit would be properly named if it were termed the *deuthydranon* or *deuthydron* I would go a step further, however, and ask if it be not expedient to pay homage to Prout, whose prophetic contention that the elements are all of unitarian build has now been placed beyond doubt by Aston's refined measurements ? Proton might well be changed into *prouton* This would be of meaning to all who have knowledge of the history of our science

8 The *neutron* creates a difficulty, as do all things not understood We shall do well, perhaps, to await its better acquaintance before attempting to place it by name Subatomic chemistry seems to be entering upon a phase not unlike that to which we are accustomed in atomic, structural chemistry—as the evidence grows that distinct structural units, not protons alone, are concerned The use of prefixes denoting energy differences may well prove to be desirable *Cataprouton* might serve as an alias of neutron in this event *Balliston* is another possibility, as it is a mere missile

9 The argument applies equally to electrons, now that so called positrons are claiming attention Might not these be brought under the Faraday hat ? Are such terms possible as an , ano or anodoelectron and cath , catho or cathodoelectron ? At present, the *on* is a mere terminal, without special significance An alternative would be to speak simply of l and d electrons, according to the twist given to them in the magnetic field

10 One other task that we have long shirked may be considered here—the naming of elements in the alternative states of atom and molecule Lavoisier drew a clear distinction between *oxygen*, the stuff in oxygen compounds, on one hand , and *oxygen gas*, on the other We now symbolise the difference by writing O and O_2 Hydrogen and oxygen are the stuffs in water—why not use the names only with this significance and term the gases *Dishydrogen* and *Disoxygen ?* We have no hesitation in speaking of dimethyl and diphenyl Ozone then becomes tris oxygen Maybe the now conventional *ion* terminal makes such change unnecessary though this is only applicable to hydrogen in salts The long familiar term *radicle* also still holds the field Probably together these terms will suffice in any case too many *radical* changes are undesirable

Rubber-Growing Research in the U.S.S.R.

A DETERMINED attempt to make Russia independent of imported rubber in a few years' time is being made by investigating the possibility of home grown rubber, and by the manufacture of 'synthetic rubber' , four factories are already engaged in the industrial production of the latter Research on the growing of rubber is carried out at two rubber institutes working in conjunction with the Institute of Plant Industry. Expeditions have been sent out to search at home and abroad for suitable rubber bearing plants, the indigenous flora having been particularly carefully surveyed

The three most promising plants so far appear to be *Parthenium argentatum*, Gray, *Scorzonera tau-saghys*, and *Taraxacum gymnanthum*, D C The first-named, the guayule, brought from Mexico, has been the subject of several investigations[1] This plant has several varieties, differing in rubber content, resistance to drought and cold, and also in the quantity and germination of seed produced, easy propagation by seed is important for the economical production of rubber from this type of plant

Scorzonera tau saghis grows wild in Central Asia, and was first described by the staff of the Institute in 1931 It is a slow growing perennial, very readily reproducing itself vegetatively, and is rich in best quality rubber *Taraxacum*, a biennial, occurs in the south of the Crimea Loman, Kotov and Tcherkasov have described the last two[2] These indigenous plants have not been under observation so long as the guayule, but are considered very promising owing to the high quality of their rubber and the ease of separating it The two native plants are also noteworthy for a low proportion of resin to rubber, and the fact that the rubber contained in them is in the form of fine threads, this form of occurrence has not been encountered previously by the investigators

Experimental plantations of the first two plants named above are in existence, many of them large enough to enable the trials to be carried out on a commercial scale It has been planned to have more than 500,000 hectares under rubber cultivation by 1937

University and Educational Intelligence

CAMBRIDGE —The governing body of King's College, having made provision for four additional fellowships open for competition to graduate members and research students of the University, offers for competition a fellowship in mathematics including theoretical physics to be associated with the names of the late Arthur Berry and Frank Ramsey Further information can be obtained from the Provost, to whom applications should be made by November 1

LONDON The title of reader in aeronautics in the University has been conferred on Dr N A V Piercy, East London College

Prof Karl Pearson has been appointed Heath Clark lecturer for the year 1934

WALES —The Council of University College, Aberystwyth, has accepted with regret the resignation of Principal Sir Henry Stuart Jones on the grounds of ill health Prof Gwilym Owen, professor of physics, has been appointed acting principal of the College for the remainder of the current session

A memorial tablet to the late Principal J H Davies has been unveiled in the College quadrangle

RESEARCH in chemistry and physics will be heavily subsidised by the United States Federal Government if a bill lately introduced into the House of Representatives for the establishment of research fellowships should be passed into law According to a Science Service report of January 19, the bill proposes that the Secretary of Commerce be given twenty million dollars for this purpose Any citizen with a bachelor's degree who demonstrates, by examination, his suitability, would be put to work under a university professor It is open to question whether the scheme is as sound as the Wisconsin plan (NATURE, 132, 977, Dec 23, 1933), for relieving professors temporarily of all teaching duties in order to enable them to devote themselves to research

Science News a Century Ago

Royal Society

On April 10, 1834, Mr J W Lubbock, treasurer, in the chair, nineteen further candidates were elected into the fellowship, contrasting with to-day's limit of seventeen allowed in a whole year Their names were —Viscount Adair, Charles Ansell, Felix Booth, Lieut Alexander Burnes, Francis Corbaux, Sir William Folkes, James W Freshfield, John Davies Gilbert, Edward Griffith, Edmund Halswell, Dr William Henry, Robert Hudson, the Rev William F Lloyd, John Phillips, Capt Walter N Smee, William Spence, Henry S Thornton, Dr John Warburton, Horace H Wilson

Among the newly elected in the above list, some names suggest special reference Felix Booth was a munificent patron of arctic and antarctic exploration Lieut (afterwards Sir) Alexander Burnes was a distinguished Indian officer who explored the Punjab, Afghanistan, and Bokhara, in 1830 33 Returning to England in 1833 he received a great welcome In 1841 Burnes met with a tragic fate, being killed by Afghan insurgents John Phillips, geologist, was a nephew of William Smith, the father of English geology In 1853 Phillips succeeded Strickland as deputy reader in geology at Oxford, three years later on the death of Buckland he was appointed to the professorship William Spence, entomologist, collaborated in many publications with William Kirby elected into the Society sixteen years earlier

Death of John Fuller

On April 11, 1834, John Fuller of Rose Hill, Sussex, who founded the Fullerian professorships at the Royal Institution, died in Devonshire Place at the age of seventy seven years In 1777 he had succeeded to the estate of his uncle Rose Fuller M P for Rye, and three years later was elected M P for Southampton, holding his seat until 1784 Made Sheriff for Sussex in 1797, in 1802 he was elected M P for the county after a contest lasting sixteen days and costing him £20,000 in addition to a purse of £30,000 subscribed by the county He sat until 1812 On one occasion in 1810 Fuller made a scene in the House, was taken into custody and severely reprimanded by the Speaker At Rose Hill he erected an observatory He was buried on April 18, 1834, in the family vault at Brightling, Sussex

James Bowman Lindsay

On April 11, 1834, the *Dundee Advertiser* published the following advertisement J B Lindsay resumes classes for cultivating the intellectual and historical portions of knowledge and instruction on April 14, 1834, in South Tay Street, Dundee In a few weeks hence a course of lectures will be formed on frictional, galvanic, and voltaic electricity, magnetism, and electromagnetism The battery, already powerful, is undergoing daily augmentation The light obtained from it is intensely bright, and the number of lights may be increased without limit A great number of wheels may be turned by electricity, and small weights raised over pulleys Houses and towns will in a short time be lighted by electricity instead of gas, and heated by it instead of coal, and machinery will be worked by it instead of steam—all at a trifling expense A miniature view of all these effects will be exhibited, besides a number of subordinate experiments, including the discoveries of Sir Humphry Davy " Lindsay was born in 1799 and died in 1862

Self-Instruction in Chemistry

The popularity of chemistry a century ago is recalled by an article entitled Practical Helps to a Cheap Course of Self Instruction in Experimental Chemistry ', contained in the *Mechanics Magazine* for April 12 1834 The extensive utility of chemical knowledge the writer said has caused it to be very generally nay almost universally cultivated but it is a branch of philosophy so entirely founded on experiment that no person can understand it so as to verify its fundamental truths unless he conducts experiments himself A notion that a laboratory fitted up with furnaces and expensive and complicated apparatus is absolutely necessary to perform chemical experiments is exceedingly erroneous , in fact diametrically opposite to the truth For all ordinary chemical purposes and even for the prosecution of new and important inquiries very simple means are sufficient The writer gave a list of pieces of apparatus and of the substances which should be obtained the whole of which were considered to be in the reach of persons of even the most modest means and intending experimenters were advised to purchase their chemicals from either Mr Dymond 146 Holborn bars or Mr Davy 390 Strand

FitzRoy on the River Santa Cruz

On April 13, H M S *Beagle* anchored in the mouth of the Santa Cruz where she remained until May 12 On April 18 Capt FitzRoy set out with three whale boats to explore the river and was away until May 8 Darwin accompanied the expedition and his Diary contains an account of the work done The party consisted of twenty five souls all well armed and capable of defying a host of Indians With a strong flood tide & a fine day says Darwin we made a good run, soon drank some of the fresh water & at night were nearly above the tidal influence The river here assumed a size & appearance which even at the highest point we ultimately reached was scarcely diminished It is generally from three to four hundred yards broad & in the centre about seventeen feet deep , and perhaps its most remarkable feature is the constant rapidity of the current, which in its whole course runs at the rate of from four to six knots an hour In so strong a current it was of course quite impossible either to pull or sail, so that the three boats were fastened astern of each other , two hands left in each & the rest all on shore to track (we brought with us collars all ready fitted to a whale line) The tracking party was divided into two and *every one* pulled in alternate spells of one and a half hours '

On April 22, Darwin records The country remains the same, and terribly uninteresting The great similarity in production is a striking feature in all Patagonia " On April 29, he says, from the high land we hailed with joy the snowy summits of the Cordilleras, as they were seen occasionally peeping through their dusky envelope of clouds' On May 4, the party was about 140 miles from the Atlantic and 60 miles from the nearest inlet of the Pacific, and here they ' took a farewell look at the Cordilleras which probably in this part had never been viewed by other European eyes, & then returned to the tents" By May 8, they were back at the mouth of the river where they found ' the Beagle with her masts up, freshly painted, & as gay as a frigate"

Societies and Academies

LONDON

Mineralogical Society, January 25 JAMES PHEMISTER Zoning in plagioclase feldspar The paper describes various types of zoning in plagioclase feldspar in the calciferous sandstone basalt lavas in one district of Scotland The zoning is classified as (*a*) normal (*b*) simple reverse (*c*) oscillatory Simple reverse zoning is associated with other differences in the zones which point to important time intervals between the growth of the zones Oscillatory zoning classified as oscillatory normal and oscillatory reverse and attention is directed to the occurrence of oscillatory zoned crystals which show no general *tendency towards either more calcic or more sodic* plagioclase Distinction is drawn between the main zones and the thin shells of alternately more and less calcic composition within the main zones The alternating composition of the thin shells is possibly the result of lack of balance between rate of growth of the crystal and rate of diffusion from the surrounding magma Recurrence of calcic plagioclase in the inner part of main zones is explained as the result of eruption of hot magma into the crystallising liquid probably consequent on eruption of lava at higher levels H H READ On zoned associations of antigorite talc actinolite chlorite and biotite in Unst Shetland Islands In an injection zone within the staurolite kyanite garnet gneisses of western Unst occur spherical or ellipsoidal bodies up to 20 ft in diameter composed of an interior of antigorite followed outwards by an orderly sequence of zones made up entirely of talc of actinolite of chlorite and of biotite It is considered that the zoned bodies result from the fragmentation of peridotite sills during the staurolite kyanite garnet metamorphism, followed by the entry of fluids into the masses during injection metamorphism and the formation of the zonally arranged layers At the same time, material displaced from the masses reacted with the country rock to give the biotite zone Transitions to the country rock were mostly pared away during the later chloritoid and chlorite producing metamorphisms that have affected the staurolite kyanite garnet gneisses M H HEY and F A BANNISTER Studies on the zeolites (7) Clinoptilolite, a silica rich variety of heulandite Rotation photographs of a single crystal from the original specimen of clinoptilolite (so called 'crystallized mordenite of L V Pirsson) show that it is a silica rich variety of heulandite The chemical composition and optical properties are in agreement with this interpretation The mineral bears no relation to ptilolite B RAMO RAO and A BRAMMALL Notes on cordierite in the Dartmoor granite Two groups of associated, but as yet unrelated, facts were recorded concerning the sector twinned cordierite in the garnetiferous granite of Sweltor (1) an aggregate of cordierite grains is separable into fractions varying in composition , in particular, the molecular ratio FeO/MgO varies from 0 37 to 1 28 in six intermediate fractions analysed, the ratio for the aggregate being 1 52 (2) all sectors are optically negative, but the value of $2V$ varies between 56° and 72° Centrally paired sectors give the same $2V$ value, whereas adjacent sectors often give different values, the maximum difference observed being 12°

Physical Society, February 2 S R Rao and G Sivaramakrishnan A new method of determining the magnetic susceptibilities of gases and vapours Compensation is effected for the test bulbs , and the influence of surface condensation, if any, of gases and vapours can be allowed for Electromagnetic re torsion is employed and the arrangement is rendered independent of small changes in the magnetising current The molar susceptibility of carbon dioxide was found to be $-(20 79\pm0 08)\times10^{-6}$ L R Wilberforce Magnetised ellipsoids and shells in a permeable medium The probability that the field round a thin normally magnetised shell is independent of the permeability of the medium surrounding it is discussed W D Wright and F H G Pitt Hue discrimination in normal colour vision Hue discrimination curves have been obtained for five normal observers the apparatus and method of observation are described and the results discussed Two minima in the discrimination curve are found at about 0 60μ and 0 49μ and a secondary minimum at 0 45μ The curves are appreciably different from those normally reproduced in textbooks particularly at the red end of the spectrum where a secondary minimum has generally been shown N R Tawde Intensity distribution in molecular spectra N_2 second positive system Intensities of bands in the $c^3\pi\rightarrow b^3\pi$ system of N_2 under four different conditions of excitation have been measured by means of calibrated photographs of the spectrum transition probabilities derived from these have been compared with the Condon parabola as obtained from Morse s and Rydberg s potential energy functions effective temperatures have been derived on the assumption of a Boltzmann distribution for vibrational energy

Dublin

Royal Irish Academy, January 22 Joseph Algar and John P Flynn A new method for the synthesis of flavonols Flavonols may be prepared in small yield, by the oxidation of flavindogenides of the type 3 benzylidene flavanone in alcoholic alkaline solution by means of hydrogen peroxide Considerably better results are obtained by adding 30 per cent hydrogen peroxide to a solution of an *o* hydroxyphenylstyryl ketone in hot alcoholic potash The preparation in this manner, of a number of flavonols is described Since *o* hydroxyphenyl styryl ketones are readily prepared the reaction affords a convenient method for the synthesis of flavonols The products are readily purified and in most cases satisfactory yields (20–40 per cent) are obtained

Edinburgh

Royal Society, March 5 E B Bailey and W J McCallien The metamorphic rocks of north east Antrim The schists of Antrim fall into the following Scottish groups Ben Lui Schists, Loch Tay Limestone, Pitlochry Schists, Green Beds, Ben Ledi Schists The Loch Tay Limestone outcrops at Torr Head and passes north westward under the Ben Lui Schists The local evidence does not definitely decide whether this is due to inversion or not The main interest is the occurrence of green beds on two distinct structural levels, the lower at Leckpatrick and Loughaveema, the upper at Runabay Head and Cushendun Bay This is probably caused by recumbent folding of a single horizon Support is thus lent to Clough's interpretation of Cowal Other features of the district are the prominence of albite schists in the Pitlochry and Ben Ledi groups and the frequent development of hornblende in the green beds This last is largely attributed to alteration by the Cushendun granite Robert Carrick Spermatogenesis of axolotl (*Amblystoma tigrinum*) The haploid chromosome number in the male is fourteen plus a small accessory chromosome which usually divides in the first maturation division This division is the meiotic one and is preceded by parasyndetic union of homologous chromosomes Pairing is initiated at the proximal pole of the nucleus and the polarised homologues twist about each other from the very onset of syndesis equivalent chromomeres along their length being brought together during the process Amitotic division does not occur among primary spermatogonia Details of spermogenesis are not discussed P Ch Koller Spermatogenesis in *Drosophila pseudo obscura* Frol (2) The cytological basis of sterility in the hybrid males of races *A* and *B* The chromosome behaviour of the sterile hybrid male during spermatogenesis is highly abnormal The chromosomes remain univalent usually in the first meiotic division aneuploid and sometimes polyploid spermatids are formed which degenerate The chromosomes of races *A* and *B* are at least partially homologous and they are associated in the hybrid female Therefore it is suggested that the cause of anomalous chromosome behaviour is genetical Complimentary genetic factors are responsible for the sterility of hybrid males Thomas Nicol Studies on the reproductive system in the guinea pig observations on the ovaries with special reference to the corpus luteum Data for forty female guinea pigs are analysed If several corpora lutea are formed at the immediate post partum ovulation and the animal becomes pregnant all of these persist and become corpora lutea of pregnancy whether or not all the ova were fertilised Numbers of new and old corpora lutea seldom correspond in the same female Prenatal mortality is 29 5 per cent and seems chiefly due to lack of fertilisation of the ova shed No evidence for alternating action of ovaries or that migration of ova occurs In subsequent pregnancies the uterine horn used is a matter of chance

Leeds

Philosophical and Literary Society, December 12 C W Gilham The condition that a certain integral may be rational The invariant condition that the integral $\int fdx/\varphi^2$ should be rational in value is obtained f and φ being polynomials of degrees seven and three respectively R Whiddington and F C Poultney Note on the photographic intensity measurement of moving electron beams A very brief account of a method of comparing electron beam currents of widely different values by moving the beams across a photographic plate at known rates and comparing the resulting densities of the traces R Whiddington Note on a new transition produced by electron impact in helium This note refers to a letter in Nature of June 24, 1933, where it was pointed out *inter alia* that electrons of a few hundred volts energy produced, in addition to the well known $(1^1S_0 - 2^1P_1)$ transition of 21 1 volts, another line at about 42 volts corresponding to two successive collisions by the same electron and yet a third line at about 60 volts Careful measurement of this last line shows it to correspond to a loss of 59 2 volts It cannot therefore be due to the process $3(1^1S_0 \rightarrow 2^1P_1) = 63 3$ volts—a result not unexpected in view of the high probability of the transition as shown by the density of the line in the photographs It is likely to be due to some multiple excitation in which the same impacting electron within the atom carries out more than one process—such for example as simultaneous excitation of the two atom electrons or even possibly ionisation plus excitation H M DAWSON and N B DYSON The rate of hydrolysis of bromoacetic acid in relation to its degree of ionisation The marked fall in the rate of hydrolysis of bromoacetic acid which is observed when the hydrogen ion concentration is increased by the addition of a strong acid cannot be attributed to the elimination of the reaction which depends on collisions between bromoacetate ions and water molecules On the contrary the fall is mainly due to the reduction in the velocity of the hydrolytic process which is primarily due to collisions between bromoacetate ions and bromoacetic acid molecules J W BELTON The kinetic interpretation of the activity coefficients of non electrolytes The activity coefficient of a non electrolyte in presence of an electrolyte is dependent on the adsorption potential at the solid liquid interface The expression derived is in qualitative agreement with experiment C H DOUGLAS CLARK Spectroscopy and valency (2) The periodic groups of non hydride diatomic molecules The classification of non hydride diatomic molecules into their appropriate periodic groups becomes possible according to various combinations of (1) two groups of non bonding electrons (nine kinds) and (2) one group of shared electrons (twenty kinds) The groups resemble those of the Periodic Table and are divided in a similar way into *A* and *B* sub groups The new table possesses the leading advantages of the older classification Further discussion is to follow C H DOUGLAS CLARK An interconversion scale for energetic and related magnitudes in the electromagnetic wave band Interconversion of the magnitudes wave length wave number frequency electron velocity mass temperature corresponding to maximum energy energy in electron volts ergs calories and kilogram calories per gram molecule may be conveniently accomplished by means of a scale covering the electromagnetic wave band over 90 octaves from λ 10^{20} to ($\approx$) 10^{-7} A Advantages of the scale in spectroscopic and general work are noted with special reference to losses of mass occurring on assembling *atomic nuclei from their constituent* parts and to the temperature corresponding to energy of maximum density L LOOSE W H PEARSALL and F M WILLIS Carbon assimilation by *Chlorella* in Windermere Measurements of oxygen production by *Chlorella vulgaris* at different depths in Windermere show that carbon assimilation exceeds respiration on an average August day to a depth of ten metres which also represents the depth of the epilimnion at that time Cell division was apparently most rapid below this depth but cell extension and cell mortality are highest nearest to the surface

PARIS

Academy of Sciences, February 12 (*C R* 198 625 684) V GRIGNARD The preparation of certain organomagnesium compounds by removal In cases where the yield of the organomagnesium compound is small or nothing the addition of a solvent such as ethyl bromide which appears to keep the surface of the magnesium clean has been found to give good results The method has been successfully applied to *p* bromveratrol *p* dibrombenzene and similar difficult reactions LOUIS ROY The conditions of visibility and the separation of a satellite star J TOUCHARD A problem of permutations ALFRED ROSENBLATT *Non linear m harmonic equations* with two independent variables ANTOINE MAGNAN and CLAUDE MAGNAN A chronophotograph with ultra rapid recording The apparatus described and illustrated is designed to give 30 000 images per second MICHEL LUNTZ and PAUL SCHWARZ Circular alternated eddies GEORGES BRUEL Map of the Moyen Ogooué to the sea (1/500 000) of A Meunier (1932) AL PROCA Particles that may be associated with the propagation of a light wave LÉON and EUGÈNE BLOCH A new spectrum of zinc Zn IV JEAN SAVERNIN Polarisation by remote diffraction at the rectilinear edge of a steel screen JEAN BOUCHARD Influence of the solvent on the law of variation of the fluorescent power of certain colouring materials as a function of the concentration of their solutions AUGUSTIN BOUTARIC and MARIUS PEYRAUD The relation between the ascent of colloidal granules in porous bodies and their adsorption in the support in which the rise takes place O BINDER Action of aqueous solutions of copper sulphate on cupric hydroxide Both the method of Schreinemakers and X ray analysis lead to the conclusion that the definite compound $4CuO\,SO_3\,4H_2O$ is the only substance produced by the interaction of aqueous solutions of copper sulphate and cupric hydroxide DANIEL MOTARD The alkaline bismutho iodides A VILA The rapid microdetermination of phosphorus in organic products The ammonium phospho molybdate precipitate is measured in a special form of tube after centrifugation CH PRÉVOST and I OSSON The knowledge of the stycerols MARIUS BADOCHE The preparation of 1 1 3 triphenyl 3 carboxy rubene $C_{33}H_{22}CO_2H$ and its alkaline salts MARCEL GODCHOT and MLLE GERMAINE CAUQUIL The active *cis* and *trans* 1 methyl 3 cyclohexanols HENRI CLÉMENT The organo magnesium compound of pentamethylbenzene This compound cannot be obtained by the usual method but on adding some ethyl bromide as suggested by Grignard the reaction takes place normally with good yields S GOLDSZTAUB The crystalline structure of iron oxychloride Results of a complete X ray study JACQUES DE LAPPARENT The constitution and origin of leverrierite C ARAMBOURG The eruptive formations of Turkana (Eastern Africa) MME E JÉRÉMINE The volcanic rocks on the western edge of Lake Rodolphe TONY BALLU The condition of the soil and the effect of an agricultural tractor CHARLES ROUSSEAU The structure of the hepatic epithelium of the eolidians MLLE ANNE RAFFY The influence of variations of salinity on the respiratory intensity of *Telphusa* and crayfish C LEVADITI A VAISMAN and MLLE R SCHOEN The biological properties of the syphilitic virus contained in the residual syphilomes of treated animals FERON and ANDRÉ LANCIEN The association of the cinnamic radical and copper in the treatment of leprosy After prolonged study (four thousand injections) the author concludes that the cupro cinnamic complex probably attacks the root of the disease It is painless and can be injected even in very young subjects If it does not always cure there is scarcely a case in which it cannot bring about marked improvement

Forthcoming Events

[*Meetings marked with an asterisk are open to the public*]

Sunday, April 8

BRITISH MUSEUM (NATURAL HISTORY) at 3 and 4 30 Capt Guy Dollman The Evolution of the Horse *

Monday April 9

VICTORIA INSTITUTE at 4 30 Mrs A S D Maunder Early Hindu Astronomy

ROYAL GEOGRAPHICAL SOCIETY at 5 —Capt M Hotine The East African Arc of Meridian

Friday April 13

ROYAL SOCIETY OF ARTS at 4 30 J H Field Indian Meteorology

INTERNATIONAL RADIO CONGRESS April 10–15 —To be held at Warsaw

FARADAY SOCIETY April 12 14 —General discussion on The Determination and Interpretation of Dipole Moments to be held at Exeter College Oxford

GEOGRAPHICAL ASSOCIATION April 13 14 —Spring Conference to be held at Glasgow

Agricultural Marketing Boards in Great Britain

THE marketing of agricultural produce is much more difficult than that of factory produce The time element dominates production in spite of all advances in science, a cow still takes nine months to produce a calf and a ewe takes five months to produce lambs by no known method can these processes be hastened and still more months have to elapse before either calf or lamb is of much value as food Seed time and harvest come much as they did a thousand years ago wheat is still in the ground some eight or nine months before it is ready for cutting However, while plants and animals move slowly prices change rapidly, and it has happened frequently in recent years that farmers have started the production of lamb milk or bacon on perfectly sound methods fully in accordance with the prevailing level of prices but long before the commodity was ready for sale prices had changed so drastically as to involve the farmers in heavy financial loss Obviously science could do nothing to help the trouble was purely economic

Further until recently farmers produced only one or two commodities on contracts in the main they produced simply in hope of a favourable market Only because they happened to be thrifty people trusted by merchants and bank managers has it been possible for them to keep going during the past few years

Until a few months ago the agricultural situation had been rapidly getting worse and even the most stable farmers in Great Britain found themselves in financial difficulties An agricultural crisis at the present juncture had obviously to be avoided, and the Minister of Agriculture went straight to the heart of the matter and took economic measures to deal with an economic problem Improvements in marketing were worked out

Two types of methods have been adopted For wheat, the farmers of Great Britain are guaranteed a definite share of the home market at a definite price level The share is called the 'quota', and the difference between the agreed price and the ultimate market price is borne on the general wheat account of the country and not by the Exchequer Actually there has been no appreciable rise in price of bread, but the quota, while sufficient for agriculture, is only a small part of our total consumption, so that disparities in price between English and imported wheat would scarcely be likely to have much effect on the price of the final loaf

For meat, milk and potatoes, other methods were adopted We already produce something like half our total meat supply, the whole of our liquid milk, and almost the whole of our potatoes Any increase in price paid to the farmer would therefore be felt sharply by the consumer, to whom the distributor would certainly pass it on The method adopted has been to set up Marketing Boards' to assure that the produce of the British farmer, at any rate up to a specified total, should find a market The details of working do not concern us here they have necessarily to vary with the commodity There is a general disposition among farmers to accept the schemes, with all the restrictions they imply The farmer is now finding that under these new conditions he cannot produce what he likes and sell how he likes having accepted the protection of the new Boards he must conform to their regulations The result is virtually to put agricultural production on to a contract basis, just as most manufacturing production is done, but the farmer is in the somewhat more favourable position that he can, if necessary, produce much of his own raw materials

It is obviously essential to the success of the scheme that production should be as economical and efficient as possible, and that all wastes and losses should be reduced to a minimum Power has therefore been given to the Boards to undertake or foster scientific research wherever this is deemed necessary This provision need not, and should not, cut across existing provision made by the Ministry of Agriculture and financed out of the Development Fund There are at present some twelve research institutes, at Rothamsted, Cambridge, Oxford, Aberdeen, Reading, Long Ashton, East Malling, and elsewhere, concerned with research into the various aspects of agricultural science and practice soils, plant nutrition, plant pathology, plant genetics, animal nutrition, animal health, animal genetics, dairying, fruit and others These institutes exist for the purpose of gaining knowledge, which is then (in principle, at any rate) passed on to the county agricultural staffs to be sorted out by them, so that information of interest to the farmers of any particular region may be given to them Various methods are adopted by the different institutes for actually effecting the transmission of information, and it is admittedly a difficult business, but it is done

The powers now conferred upon the Marketing Boards will enable them to keep in touch with the research institutes and ensure the systematic collection and dissemination of existing knowledge, and the completion of work necessary for filling gaps The Potato Marketing Board, for example, will certainly find that a great deal remains to be discovered about the growth and storage of potatoes A conference was recently called at Rothamsted, dealing with these very problems and by a fortunate circumstance its chairman was also chairman of the Potato Marketing Board But the papers and the discussion revealed many important problems on which existing information is quite inadequate More will clearly have to be obtained, but the work must be focused on the problems of the potato grower on the production, the quality, the keeping powers, and the avoidance of diseases and pests of the potato crop

Two methods will probably need to be adopted by the Boards The appropriate existing institutes can be strengthened to deal with specific problems this is not likely to be costly and it will so far as it goes, be economical and effective But the second method is at least as important It is to set up a small experiment station devoted exclusively to the study of the crop concerned and place it in the midst of the chief growing region, so that growers can easily visit it and the staff can keep themselves fully posted in the growers problems and difficulties

Three such stations have already been in existence for some time, and their success testifies to the value of the method the Fruit Research Station at East Malling, the Fruit and Cider Research Station at Long Ashton, Somerset, and the Nursery and Market Garden Research Station at Cheshunt, which devotes itself mainly to tomatoes and cucumbers, the chief products of its district All these, especially the two former, are larger than would be needed by the Marketing Boards, but the general type would serve well The Cheshunt Station affords the best model its committee is appointed partly by the growers and partly by the Rothamsted Experimental Station Committee, its staff is in close touch with Rothamsted and with the Plant Physiology Department of the Imperial College of Science, but at the same time it is so close to the growers that it misses none of their difficulties It has achieved remarkable success A Potato Research Station situated in one of the chief potato growing districts, but so organised as to be in close touch with the appropriate research institutes, would under suitable management be expected to be similarly successful It is however important that the staff should be men of sound scientific training and outlook the good practical growers already know all that the so called practical man can teach them and the only one likely to be of help is the scientific worker experienced enough to show that he can use the tools of science for solving practical problems and young enough to be able to adapt himself to the conditions of an important industry and to throw himself whole heartedly into the new work

Sugar beet is another crop that deserves very serious scientific attention Happily a research scheme has now been set on foot in which the sugar beet factories are co operating with Rothamsted the National Institute of Agricultural Botany the Oxford Institute of Agricultural Engineering and the Norfolk Agricultural Station each of which undertakes a particular group of problems For the moment the scheme is only on a year to year basis and so it loses the efficiency that comes only with a longer time basis nevertheless the fact that it is working shows a sound spirit of appreciation of the value of scientific assistance for its growers on the part of those responsible for the factory organisation

The Endocrine Glands

The Tides of Life the Endocrine Glands in Bodily Adjustment By Dr R G Hoskins Pp 352+8 plates (London Kegan Paul and Co Ltd 1933) *15s net*

THIS little book has been written by the Director of Endocrine Research in the Medical School of Harvard University and we must congratulate the author on his performance He has produced an admirably written manual which will be of the greatest service to all desiring the latest information about the structure and functions of the endocrine glands What especially awakens our admiration is the note of scepticism and caution which colours his language when he is relating the latest extravagances of those endocrinologists who claim to be able to resolve character and personality into endocrine chemistry This same caution leads him to view with grave doubt the theory of Sir Arthur Keith that the structural differences between human races are due to differences in endocrine development He points out that according to this theory the Negro should exhibit defective sexuality since Keith attributes this melanism to a defective adrenal development but it is notorious that the very opposite is the case

Our chief complaint against the author is that he has a strong tendency to over estimate the part played by his countrymen in this field of research The diagnostic feature of an endocrine gland is that it produces a hormone and it is only on page 300 that we reach a brief account of the foundation research of Bayliss and Starling which initiated this whole province of biological investigation and it is mentioned quite casually— indeed the word hormone was first used in connection with this research Assuredly it was Bayliss and Starling invented the term and defined what they meant by it

It seems to us too that the author loses his usual caution in his enthusiasm for some very recent results obtained by American workers—as for example those of Cannan When we are told that an animal suffers no inconvenience when its entire chain of sympathetic ganglia is cut out most of us will become deeply thoughtful—and wait

The author raises some extremely interesting questions during his discussions and to two of these we propose to allude briefly The first of these concerns the constitution of the cells which make up the male and female bodies respectively On the sex chromosome theory the tissues of male and female should have different growth capacities since the nuclear constitution in all the cells of the male body is different from what it is in those of the female But as the author remarks this difference must be potential only for these tissues obstinately refuse to produce the appropriate secondary sexual differences unless they are flooded with the sexual hormones But he could have gone further and said that grafting experiments proved that the tissues of both males and females with judicial impartiality will produce the secondary sexual organs of *either* sex if exposed to the action of the appropriate hormone so that the difference in nuclear constitution seems to be without effect

Another question discussed by the author is the evolutionary origin of the endocrine organs How did a tiny group of cells constituting a minute fraction of the substance contained in the body acquire its tremendous powers ? On the chance theory of the origin of variations how did Nature chance to construct organs of such enormous potency ? Now in the case of two of the most important of these organs comparative embryology has supplied the answer and has shown that here, as in all properly analysed cases of evolution, development has been slow, functional and continuous.

The thyroid gland of *Amphioxus* begins as a growth, the so-called endostyle, in the mid-ventral line of the pharynx: this groove carries lines of ciliated cells and intervening lines of mucus-producing cells. By their joint aid a cord of mucus is produced which is worked forwards to the mouth, where it is broken up into a network of filaments by the inrushing current of water produced by the cilia lining the gill slits. The tiny organisms, plant and animal, borne in the water are entrapped and the net with its living prey carried back to the intestine and swallowed. The iodine necessary to all animals is thus secured, since the microscopic plants are a potent source of it. (It is curious to find the author describing the endostyle of *Amphioxus* as a "pouch of the gut producing a mucus which probably aids digestion". Such an answer given by an English medical student sitting for his first M.B. examination would get a very black mark from his examiner.) There is nothing mysterious about the thyroid or endostyle' of *Amphioxus*. Similar adaptations are found in a number of aquatic invertebrates belonging to quite different classes—such as bivalves and gastropods amongst the Mollusca—and their purpose is the same as that of the endostyle.

In the case of the lamprey, whose larval life is much longer than its adult existence, the endostyle is still present in the larva and functions in the same way as in *Amphioxus*, but now it has become restricted in extent and forms a pouch studded inside with groups of mucus-producing cells, which opens into the pharynx by a narrow opening. In the adult lamprey the pouch is cut off from the pharynx, and breaks up into a number of mucus-producing vesicles; no longer able to obtain iodine from outside, it must secrete it from the blood.

Here we have the familiar phenomenon of the gradual restriction of powers originally exercised by a wide stretch of tissue to a small portion of it, and the likewise familiar but totally inexplicable phenomenon of Nature learning to produce from the internal resources of an animal something originally obtained from outside. The gas in the air-bladder of fish is a case in point. Originally the air-bladder was a mere pouch of the pharynx, the use of which was to retain bubbles of air swallowed by the fish when the oxygen tension in the water was becoming low. But it also served to give the fish the power of adjusting its buoyancy, and in the majority of fish the air-bladder is shut off from the throat and the gas contained in it is secreted from the blood. Evans has recently shown that in fresh-water fish in which the connexion with the throat is maintained, only part of the contained air is obtained by swallowing; most of it is secreted by the blood.

The other endocrine organ of which the evolutionary history has been traced is the pituitary body, including both anterior and posterior lobes. This mysterious body has been credited with the production of at least six different hormones. In the ascidian tadpole, however, in which a brain vesicle, distinct from a spinal cord, first makes its appearance, the pituitary appears as a tube connecting the vesicle—not with the digestive system as our author states—but with the stomodæum or ectodermal hall-way to the mouth. At the metamorphosis, the part connected with the mouth becomes cut off from the rest and develops a number of glandular pockets. In a word, the pituitary body was originally nothing more than the anterior neuropore. In the primitive vertebrate, which as we have seen was originally a 'filter feeder', the current of water drawn in by the cilia of the gills must also have entered the neuropore, and the extreme front end of the nervous system was thus enabled to 'taste' its contents. It thus performed exactly the same function as is exercised by the 'osphradial' ganglia of bivalve Mollusca. Later it derived the substances which it 'tasted' from the blood. Thus the inmost nature of the endocrine organs, as of every other living organ, cannot be elucidated by its structure alone; we must also take into account its evolutionary history. E. W. MACBRIDE.

Scenting the Quarry

Hunting by Scent. By H. M. Budgett. Pp. xi + 122 + 22 plates. (London: Eyre and Spottiswoode, Ltd., 1933.) 25s. net.

EVEN a Poet Laureate would find difficulty in expressing the diversity and extent of the influence of fox-hunting. Farmers, breeders, saddlers, tailors, veterinarians, surgeons, painters, sculptors, poets, composers, to name but a few, have been affected in some way or another by Reynard the Fox; and through them, innumerable others are involved. When practical experience in hunting the fox is blended with a capacity and zest for hunting data, the chase involves the world of science When, in addition, an ex-Master of the Bicester and Warden Hill Hounds discloses keen ness, perseverance, humour, and a great kindliness, the resulting expression is a book which is not merely of scientific interest, but is also endowed with a charm that can only be described by the word English

The author has succeeded in writing a book "with the object of explaining the fundamental principles of scent in such a manner that they can be grasped by those who have not had the advantage of a scientific training ' The scientific fields and coverts surveyed can only be adumbrated here in part the significance of the sense of smell, conditions under which scent is good or bad, the effects of light, temperature humidity and wind, inhalation and exhalation by the soil special experiments and apparatus (for example the author's electric scent indicator) for determining scent conditions, the nature of trails followed by hounds the examination of scent trails left by different quarries over various surfaces, the distance over which scent can be detected by various animals, olfactory fatigue, the obliteration and neutralisation of scent tracks the microscopic examination of the odorous particles forming a track, the bearing of the sense of smell on animal behaviour Especially to a dog, smelling is believing", and canines communicate with each other by means of signal posts or scent telephones" as described by Seton

The wealth of subject-matter, whether gleaned from others or from the author's original observations and experiments, is attractively presented and briefly summarised at the end of each chapter The accompanying photographs and photomicrographs, especially the plates from original drawings by such a distinguished limner of the hunting field and connoisseur of the fox as is Lionel Edwards, R I, complete an ensemble forming a quite unique contribution to intellectual and æsthetic enjoyment

The author has proved beyond all doubt, by means of painstaking experiments, that there must be actual contact between the quarry and the ground, in order to produce a trail which can be hunted by a hound Thus, a trail of scent of bruised herbage is left when an inodorous weight is dragged along a field, a trail which a bloodhound is able to follow by scent alone after forty-eight hours "Hunting by Scent" includes many other interesting observations, and also many indications of problems as yet unsolved The author, artist and publishers have produced an interesting and enjoyable volume Perhaps not the least contribution to science lies in its stimulation to further exploration of the inexhaustible field of interest of which the sense of smell is the centre

J H K

"Vulgariser sans abaisser"

The Universe of Light By Sir William Bragg Pp xi + 283 + 26 plates (London G Bell and Sons Ltd, 1933) *12s 6d* net

WE can in England, look back on a long list of eminent men of science who, so far from disdaining any attempt to popularise knowledge, have spared no pains to bring home the truths of science to the layman, and the layman has not been inappreciative of these efforts A series of some half a dozen volumes clothed in red—the Manchester science lectures for the people—tells eloquently of the crowds who thronged to the Hulme Town Hall to hear Roscoe, Clifford, Rucker, Thorpe, Huxley and a score of other famous Victorians elucidate the scientific problems of the time in a way which may seem over serious to the lighter hearts of to day, but which, if numbers be any test, was admirably suited to the needs of their hearers These lectures, born of Roscoe's energy and drive were a dominating feature in the life of Manchester in the early 'seventies of the last century In London, Faraday had not long gone from the Royal Institution, Tyndall was at the zenith of his fame, and was irritating the Scots school of physicists by his solemn championship of Mayer The persistence of force was a phrase still heard, the specific heat of electricity had still some elements of novelty, and the "Descent of Man" was a best-seller It is all very interesting, and very crinoline-ish and it is something of a surprise to realise that Boyd Dawkins, doyen of that far away group of Manchester lecturers of the 'seventies, was taking an active part in a British Association meeting some six years ago

Manchester and London were then two foci of scientific learning So they are to day, and we of the nineteen thirties are specially privileged in being able to hear Sir William Bragg's almost magically easy unravelling of the complexities of modern optical science It was all very well, sixty years since, to explore the field of spectrum analysis, or to argue the question of the formula of water, the expositor of to day, faced with an array of photons, neutrons, diplons and positrons, has a different and difficult row to hoe Sir William accomplishes the feat in a characteristically genial and effortless manner, clinching his appeal to theory by admirably conceived experiments, and stimulating the interest of his hearers (and readers) by illustrations—the laws of perspective, Japanese mirrors, rearlight reflectors, the lustre of sateen, and so forth—which keep us constantly in touch with reality *Ars est celare artem*, and, as with Boswell's report of the famous dinner episode, it seems very easy until one tries to do it for one's self

The nature of light, the eye and vision, colour and its origin, the colour of the sky, polarisation, light from the sun and stars, Röntgen radiation, and, finally, the wave and the corpuscle—this outline of the topics treated in the book shows how wide a range is covered by these lectures, which are as delightful to read as they must have been to hear Reflection at a plane surface in the opening chapter, electron diffraction at the close of the book—it is a long and involved journey which we cover in less than three hundred pages, and there is not a dull moment on the way

But surely Eros is playing an unaccustomed rôle in astronomy!

ALLAN FERGUSON

Short Reviews

Proceedings of the American Society for Psychical Research Vol 22 *The Margery Mediumship—The 'Walter' Hands a Study of their Dermatoglyphics* By Brackett K Thorogood Pp xix+228+123 plates (New York American Society for Psychical Research, 1933) n p

THIS volume is a detailed account of certain alleged supernormal phenomena which occur in the presence of the medium Margery (Mrs L R G Crandon, of Boston Mass) They consist mainly in the impressions of thumbs in dental wax, and an account by Dr R J Tillyard of the conditions under which they are produced was printed in NATURE for August 18, 1928, pp 243 ff, where Fig 6 is a photograph of one of these impressions In the leading article of the same date it was pointed out how, assuming the accuracy of Dr Tillyard's observations, we had little reason to deny the medium's power of producing the thumb prints of anyone either living or dead Since then the claim has been made that such prints of living persons (for example, Sir Oliver Lodge) have been produced, but the most interesting development is the alleged discovery that the very large number of prints said to have been made by Walter (the deceased brother of the medium and her spirit control) are in reality identical with those of a person living in Boston, who formerly attended a number of sittings and first suggested to Margery' the use of dental wax as a convenient compound

In the case of the right thumb print some forty points of similarity are admitted by both sides in the case of the left, identity appears to be absolute, although the president of the American Society for Psychical Research now claims that the examples printed previously in the Society's publications were not authentic, being substitutions on the part of one of the leading investigators, through carelessness they were not noticed at the time

It is clearly impossible here to evaluate the evidence or even to discuss it, since the data on which the various arguments are based are themselves suspect Indeed the report illustrates with startling clarity the reasons why the scientific world remains aloof For from whatever point of view this report may be regarded it is not only the medium but also the officials themselves who are being denounced as incompetent and guilty of a series of dubious manœuvres

Encyclopædia of Psychic Science By Dr Nandor Fodor Pp lv+416 (London Arthurs Press, Ltd, 1933) 30s net

THIS book, in spite of its somewhat provoking title is a notable addition to the literature of psychical research The author, who, it may be said, is clearly inclined to believe far more than the evidence suggests, has nevertheless succeeded in putting together a mass of material which includes many facts pointing to conclusions not in accordance with his own The impartiality he displays in printing these data is highly commendable, and some good examples of it may be seen in the articles on Eldred and Duguid

In his preface Dr Fodor stresses the difficulties of compiling an encyclopædia of this kind, and states that he should have been assisted by an editorial committee In this we are inclined to agree Although he is fully capable of presenting his material, he is naturally not quite fully acquainted with it Thus the article on "ectoplasm" (apart from a few amazing examples of credulity) is an excellent summary, whilst that on the poltergeist is very poor In the latter article there are several cases from newspapers whereas there is no word of Dibbesdorf, of Stans, or of Oakland, California! Similarly, in the body of the text we find omissions for which it is not easy to account Among these we would mention Farmer Riley, Abraham Cummings, Nicolai, Staudenmaier and the Gallery of Spirit Art Although actual mistakes are readily excusable in a work of this size, it is curious that Dr Fodor should make Patience Worth masculine, Mrs Abbott and Lulu Hurst examples of "electric phenomena", and Imoda an author of a book on psychic photography

Apart from criticisms of this kind, the book is likely to be of great service to those who wish to gain a general view of some particular aspect of psychical research or to revise a previous acquaintance The author must certainly be congratulated on the trouble he has taken, although he would be well advised to omit certain of the photographs in any later edition One of these is instructive It shows the medium Rudi Schneider when supposed to be controlled by two observers His right hand is apparently not held in any way It is a good example of what occurs in psychic science'

A Description of some Trees, Shrubs and Lianes of Southern Rhodesia By E C Steedman Pp xxi + 191 + 92 plates (Gwelo, Southern Rhodesia Miss E C Steedman, Norfolk Farm, 1933) 7*s* 6*d*

Miss Steedman is to be congratulated on having produced a book on the trees, shrubs and lianes of Southern Rhodesia which should be of great service to residents in the colony and should stimulate an interest in the vegetation of the country and also, it is to be hoped, serve a useful purpose in arresting the destruction of the indigenous timber

Miss Steedman has worked under considerable difficulties, being away from sources of botanical literature, and, in consequence, some errors in the nomenclature of the plants to which she refers have crept in This, however, is a minor point which can easily be set right when she has had an opportunity of consulting authorities and literature, should a second edition of the book be called for

Thanks to the keys and descriptions, it should be possible for anyone interested in plants to be able to identify the native species, and this will be considerably facilitated by the line drawings which are, on the whole, quite useful, though in some cases they have suffered a little in reproduction

From the purely botanical point of view, some criticisms can be offered, but the main point about the book is its value to residents in Southern Rhodesia This is enhanced by the inclusion of the native names of the trees and shrubs wherever it has been found possible to assign them to a definite species

As the work of an amateur with a real love of her subject, the book certainly deserves high commendation

A Standard Classified Nomenclature of Disease Compiled by the National Conference on Nomenclature of Disease Edited by Dr H B Logie Pp xvii + 701 (New York The Commonwealth Fund, London H K Lewis and Co, Ltd, 1933) 21*s*

The National Conference (of the United States of America) on Nomenclature of Disease was formed with the object of solving the confusion due to the absence of a standard nomenclature of pathological conditions It has now produced the system described in this book, a dual method of classifying disease, based on the two features of topography and etiology The topographical classification gives a code number to every region of the body in which disease can be clinically located, the first numeral indicates the body system, the second the organ, and the third the part of the organ involved The etiological classification similarly divides all causal factors into groups, which are further subdivided Any disease or injury has thus a number indicating location hyphened to another indicating cause The system also allows expression in symbols of obscure, undiagnosed or partially diagnosed conditions

The book can be strongly recommended to the records departments of hospitals, and as the method advocated requires accurate expression of a diagnosis, its adoption would do immense good in stimulating precise thinking and avoidance of ill defined terms on the part of clinicians

A Bibliography of Differential Fertility in English, French and German Edited by Eldon Moore on behalf of Commission II of the International Union for the Scientific Investigation of Population Problems Pp vi + 97 (London Dr E C Rhodes London School of Economics, 1933) 2*s*

The compiler of this book is not a biologist but a journalist who, like many other intelligent lay men, has been attracted by the lure of biology and the problems which it involves For a considerable time he acted as editor of the *Eugenics Review*, the organ of the Eugenics Society He has produced in this book a most valuable compilation of papers and books dealing with the problems of fertility both in man and animals

An Elementary Introduction to Physics Descriptive, Experimental and Historical By Edgar Booth Pp 465 + xvi (Glebe, N S W Australasian Medical Publishing Co, Ltd, London H K Lewis and Co, Ltd, 1933) 5*s* net

A book from Australia is to be welcomed, as it is likely to put forward fresh points of view which give hints to teachers of elementary physics in Great Britain This book is quite elementary in character and practical in type, and the author has avoided the mistake of introducing the ideas of modern physics at this early stage

Précis d'électricité théorique Par Dr Léon Bloch Deuxième édition, revue et corrigée Pp vii + 476 (Paris Gauthier Villars et Cie, 1933) 50 francs

This treatise gives an account of classical electrical theory, with modern notation and the use of vector analysis where necessary It is comprehensive and clear and ends with two important chapters, one on the electrodynamics and the other on the optics of bodies in motion

Aluminium surfaced Mirrors

By Dr H Spencer Jones F R S

THE mirrors in astronomical reflecting telescopes were formerly made of speculum metal—a hard alloy of copper and tin capable of taking a fine polish and having a fairly high reflecting power Speculum metal mirrors have been entirely replaced by glass mirrors coated on the figured surface with a thin film of silver The silvered surface when fresh has a high reflecting power for wave lengths greater than 0 375 μ at this wave length the reflecting power is 0 80 at 0 400 μ it is 0 85 at 0 450 μ it is 0 90 and at 0 700 μ it is 0 95 On the short wave length side of 0 375 μ the reflecting power falls off rapidly owing to selective absorption to a minimum value at about 0 315 μ of only 0 04 This is a serious disadvantage when observations are required in the ultra violet region Thus for example at a wave length of about 0 325 μ the atmospheric transmission is 0 50 but the reflecting power of silver is only 0 12 In a reflecting telescope the image is normally produced by reflection at two silvered mirrors so that the loss by the selective absorption of the silver is much greater than the above figures indicate

These figures refer to a freshly deposited silver film But the reflecting power steadily falls owing to gradual oxidation or to tarnishing due to the action of sulphur dioxide in the atmosphere Where such atmospheric contamination is prevalent the reflecting power falls rapidly At even the most favourable sites however there is a gradual fall in reflecting power so that the mirrors must be periodically dismounted and resilvered The silver film is easily deposited chemically and though the silvering process itself is not difficult any satisfactory method of making it unnecessary would be welcomed for it would imply that the decrease in reflecting power—which necessitates lengthened exposures and is particularly troublesome in some photometric work—had been eliminated Coating the silver film with a thin film of colourless lacquer has been tried but the optical perfection of figure is almost inevitably impaired

The development of a method of coating glass surfaces with a film of aluminium and the unexpected properties of such films are therefore of the greatest importance for astronomical observation For wave lengths greater than about 0 40 μ the reflecting power of an aluminium film is somewhat less than that of a freshly deposited silver film The difference is not however very great at a wave length of 0 50 μ the reflecting power of the aluminium film is 0 88 as compared with 0 91 for silver at 0 60 μ the relative values are 0 89 and 0 93 at 0 70 μ 0 87 and 0 95 The reflecting power of a silver film after a short period of use would soon fall below that of a freshly deposited aluminium film To the short wave length side of 0 40 μ the aluminium film is greatly superior to the silver film as it does not show the band due to selective absorption At 0 35 μ its reflecting power is 0 85 as contrasted with 0 70 for silver at 0 30 μ (near the limit of atmospheric transmission) it is 0 83 as compared with 0 08 for silver For observations in the ultra violet region the aluminium film is therefore very much superior to the silver film

The aluminium films have other important advantages A freshly deposited film on exposure to the air immediately oxidises and the oxide coating forms a protective layer which prevents the film from tarnishing It is stated by Dr J Strong who has developed at the California Institute of Technology a technique for the coating of mirrors with aluminium that concentrated nitric acid can be poured on the mirror with immunity Nevertheless the film can be readily dissolved by dilute hydrochloric acid to which a trace of some copper salt has been added Sulphur dioxide in the atmosphere does not tarnish an aluminium film or at most at a very slow rate A small mirror partly coated with silver and partly with aluminium has been exposed at Greenwich where conditions as regards sulphur in the atmosphere are bad until the silver film had become completely yellow The aluminium film was apparently unaffected Dr Strong mentions that the mirrors of a telescope aluminised in October 1932 and constantly used since show as yet no signs of tarnish

Aluminium films are more strongly adherent to glass than silver films Dr Strong states that a piece of adhesive tape may be pressed on to the film and then stripped off without loosening the metal from the glass This tenacity makes it possible to clean the surface of dust or other contamination by washing with soap and water It is also stated that aluminised mirrors do not scatter light

The largest mirror yet coated with aluminium is the 36 inch mirror of the Crossley reflector of the Lick Observatory which was coated in December 1933 When this mirror was coated with silver a long exposure spectrogram ended at about 0 325 μ An equal exposure with the aluminised mirror gives a spectrogram extending to about 0 300 μ An exposure of only 20 seconds on the star Orionis of magnitude 2 9 gave a spectrogram measurable to about 0 310 μ The atmospheric ozone absorption lines in the ultra violet can be photographed in a few seconds Dr W H Wright states that comparison of photographs of the north polar sequence before and after the aluminising indicated that the general reflectivity had been stepped up by 50 or 60 per cent this illustrates the effect of tarnishing of a silver film even under the favourable atmospheric conditions on the summit of Mount Hamilton

Aluminium is a difficult metal to sputter by cathode disintegration, and the most effective method of depositing the aluminium films has been found to be by an evaporation process in a high vacuum of the order of 0 0001 mm of mercury The aluminium is heated in small tungsten coils arranged opposite the mirror to be coated, the aluminium evaporates and condenses on the face of the mirror The low pressure enables each atom of aluminium, after evaporation, to travel in a straight path to the mirror with small probability of collision with other atoms In coating the mirror of the Crossley reflector, twelve helical tungsten coils were arranged round a 36 inch circle at a distance of 18 inches from the mirror Each coil had 10 turns and to each turn a U shaped aluminium wire, $\frac{3}{8}$ inch long and $\frac{1}{32}$ inch diameter, was clamped Each coil was connected in turn to the electrical supply, at a voltage of 20 volts the entire process of distilling from the twelve coils requiring about three minutes The mirror was placed on brass bars fastened to a reinforced steel bedplate, one inch in thickness, this arrangement enabled gases underneath the mirror to be pumped out easily The bell jar covering the mirror was of $\frac{1}{4}$ inch sheet steel, stiffened at the bottom by a rolled angle iron, and machined to give a perfect plane surface A lead fuse wire was pressed into a circular groove in the bedplate, at the bottom of the bell jar, the angle iron was bolted down by 24 bolts exerting a force of 50 tons on the fuse wire gasket, to which atmospheric pressure on exhausting added another 10 tons

The mirror surface must be absolutely clean for a satisfactory coat The most satisfactory way of securing the requisite cleanliness with a large mirror was by removing foreign material with an electric discharge from a central electrode With the arrangements used for the Crossley mirror a very uniform thickness (about $\frac{1}{10}$ μ) of coat was obtained

Dr Strong finds that it is possible to coat speculum metal gratings with aluminium, the reflectivity is increased about 50 per cent for visible light and by an even greater extent in the ultra violet The higher orders of spectrum also become relatively brighter The definition was found not to be impaired by the coating The coat can be dissolved by caustic potash, which does not attack the speculum metal This application of the process should prove of value in the laboratory as well as in astronomical spectroscopy

It is hoped that apparatus for aluminising telescope mirrors up to a size of 36 inches diameter will be available in Great Britain before long Some experimental work has been in progress, and a piece of plate glass coated with aluminium was on view at the meeting of the Royal Astronomical Society on March 9

The Lyochromes: a New Group of Animal Pigments

By PHILIPP ELLINGER and WALTER KOSCHARA, Dusseldorf

IN the observations of living animal organs by the 'intravital microscope'[1] it was noticed that cells of some organs of the animal not previously treated with fluorescent dyestuffs contained substances which were excited by ultra violet light to give a characteristic yellow green fluorescence Such substances were chiefly found in the liver cells and in the epithelial cells of the first convoluted tubules of the kidney of all the animals examined, including horses, oxen, dogs, cats, rabbits, guinea pigs, rats, mice, frogs, etc In the liver two other groups of cells could be found which were fluorescent, but far less strongly, the Kuppfer star cells, shining with a dull orange yellow fluorescence, and single cells, showing a reddish fluorescence, near to the blood vessels The two groups last named have no connexion with the pigments with which this article deals The intensity of the fluorescence of the epithelial cells of the kidney, and also of the liver cells, appeared to be diminished when the animals (rats) were fed on a diet free from nitrogen, and to be augmented after the administration of urea The suggestion arose that these pigments might have some connexion with the formation or the excretion of urea, because they were found in great quantity just at the sites of the intensive formation and excretion and therefore of great concentration of urea Since it appeared likely that these pigments had great physiological importance we tried to isolate and identify them

Animal pigments have been for a long time an object of interest to physiologists and chemists Especially by the researches of chemists, knowledge of them has been greatly increased during recent decades The animal pigments hitherto known are nearly all soluble in neutral organic solvents under suitable conditions, and this property was highly important for their isolation and recognition Only a few of the animal pigments previously known are strongly fluorescent, and their fluorescence differs in colour from that of the pigments now found in the kidney and the liver

The first attempts at extraction showed that our pigments were completely insoluble in the usual indifferent solvents, such as ether, chloroform, benzol, ligroin, and that, on the other hand, they were soluble in water As a guide in our attempts at isolation we used the characteristic yellow-green fluorescence, which clearly revealed even extremely small quantities, and which was further characterised by the fact that it was to a high degree dependent on the *p*H, being changed reversibly to a violet fluorescence by both acids

and alkalis Further, the fl
destroyed by light The solutions of our pigments are coloured orange yellow in stronger, yellow in weaker concentrations The pigments are resistant to acids, but they are destroyed by hot alkalis

After having determined the solubility of the pigments in water we proceeded, in the first instance, to mince organs fresh from the slaughter house (livers and kidneys of horses and oxen) or the same organs from recently killed dogs, in which we had determined the presence of the pigments by intravital microscopy, and, after mincing, we extracted such materials with water The watery extract was freed from albumen sugar and other contaminating substances and concentrated It appeared from these attempts that the yield of raw pigments from both organs was very small We searched therefore for another source of these pigments, promising a better yield, and found it in whey We convinced ourselves by tests that the pigments of whey correspond to those of the kidney and the liver, in respect of their fluorescence and their reactions to acid, alkali and light Having found pigments with these properties in many different materials in our first researches we concluded that we were dealing with a new group of substances of wide distribution, and we named them Lyochromes

The pigments of whey have been described recently by Bleyer and Callmann[2] and by Gerngross and Schulz[3] From the work of Bleyer and Callmann the difficulty of isolating such substances is evident Bleyer and Callmann could, indeed, greatly concentrate these substances but they were unable to isolate them They came to the conclusion that the pigment of whey belongs to the oxyproteinic acids, a conclusion which as we shall see later, cannot be maintained Whey first became useful as a raw material when we had found the right adsorbents for concentrating and isolating the pigments Fuller's earth was found to be the best adsorbent, and the adsorption v most successful from a slightly acid solution, such as that natural to whey, which always has an acid reaction due to lactic acid

From the adsorption on fuller's earth, which was washed several times with water and alcohol, the pigments were eluted by mixtures of pyridine and water[4] In this manner we obtained concentrates of pigments, which were purified by precipitation of contaminating substances, and which could be induced to crystallise from watery solution

We were able to isolate five crystalline coloured substances, which we described as 'Lactoflavins *a*-*e*'[5], and which differ from one another in constitution, crystalline form, solubility and intensity of the colour in solution It is possible, perhaps even likely, that the chromogen component in all these pigments is identical By careful removal of impurities we obtained at first three crystalline pigments, lactoflavins *a*, *b* and *c*, which are distinguished by slight solubility in water and in mixtures of concentrated acetic acid and acetone from the other lactoflavins, *d* and *e* They differ from one another in crystalline form, basicity and percentage composition as follows —Lactoflavin *b* (small hexagonal tablets, C 35 7, H 3 3 N 32 0), and lactoflavin *c* (needles of the form of a dragon fly's wings C 35 7, H 2 6 N 31 3) have a similar composition On the other hand, lactoflavin *a* (crystals in nodular aggregates, C 33 5, H 4 0, N 21 6), differs from the other two, especially by its lower content of nitrogen Lactoflavins *b* and *c* have a percentage composition close to that of uric acid (C 35 7, H 2 4 N 33 3), but differ from uric acid in their greater solubility in water and in the property of not being precipitated by ammonium chloride Lactoflavins *a* *b* and *c* have no melting points The crystals are coloured orange red They dissolve in water to give orange coloured solutions yellow when more dilute The solutions have a yellow green fluorescence It was not possible to fix the molecular weights The watery solutions lose their colour by heating with alkali with evolution of ammonia The three pigments give the murexide test

From 100 litres of whey we obtain in the most favourable case, perhaps 10 mgm of each of the three pure lactoflavins *a*, *b* and *c* Much loss is caused by the purification of the crude crystals, a procedure in which one must avoid temperatures above 60° For it was evident that on heating the watery solutions of these lactoflavins a decomposition occurred This decomposition yields a colourless substance, very difficult to dissolve in water, of a purin character and a pigment which remains in the solution, and which shows all the qualities of the Lyochromes The pigment produced by this cleavage, which we call lactoflavin *d* has been isolated by us from the mother liquors of the lactoflavins *a*–*c*, as a pigment very much more soluble in water than the Lyochromes hitherto described It is not strictly proved as yet, that this pigment from the mother liquors is identical with that formed by the decomposition of the slightly soluble Purin Lyochromes

Lactoflavin *d* crystallises in the form of reddish yellow needles, which melt at 270° 273° with complete decomposition The data per cent given by analysis (C 52 69, H 5 84, N 14 38) indicate the formula $C_{16}H_{20}O_6N_4$, or $C_{17}H_{20}O_7N_4$ The reddish yellow watery solution of lactoflavin *d* fades, on heating with alkali, to a pale yellow colour, without appreciable evolution of ammonia The murexide test gives a negative result with this pigment

In isolating lactoflavin *d* we have found a further crystalline pigment, which is precipitated in microscopic aggregates and which is called lactoflavin *e* Its solubility in water and its content of nitrogen (24 per cent) give it a position between the lactoflavins *a*–*c*, on one hand, and lactoflavin *d* on the other The lactoflavin *e* gives a positive murexide reaction, but only with chlorate and hydrochloric acid ('forced murexide test')

By a procedure corresponding to that of Warburg and Christian[6], which will be quoted later, a decomposition product can be obtained from the Lyochromes of whey by irradiation of their alkaline solutions which differs from the Lyochromes by its solubility in chloroform This substance crystallises in the form of reddish yellow small woolly needles it melts with decomposition at 315° 317 It is slightly soluble in hot water also in ammonia and is easily soluble in dilute sodium hydroxide The solutions are fluorescent in the same way as the Lyochrome solutions The results of analysis of this product of photochemical decomposition (C 61 97 H 5 19 N 20 58 per cent) indicate the formula $C_{14}H_{14}O_2N_4$ Its properties make it likely that it is at least very nearly connected perhaps identical with the substance formed by light from the Lyochromes of yeast obtained by Warburg and Christian If we accept for lactoflavin *d* the formula $C_{17}H_{20}O_6N_4$ and we compare it with the formula of the photochemical cleavage product of lactoflavin *d* a difference of $C_3H_6O_4$ is found

In the transformation of lactoflavin *d* by light we must probably reckon with a reaction proceeding in several steps At first H_2O will be split off and then a further substance free from nitrogen and finally a transformation of the nitrogen containing coloured molecule will take place On this assumption one may divide the difference between the formulæ of lactoflavin *d* and the photochemical cleavage product $C_3H_6O_4$ into H_2O (water) and $C_3H_4O_4$ (malonic acid ?) Not only the higher melting point of the cleavage product but also its behaviour to oxidation with chromic acid indicate that its molecule is more stable than the molecule of lactoflavin *d* While by oxidation with chromic acid 8 mols of carbonic acid are formed from lactoflavin *d* in about one hour and a half when the reaction comes to an end by the same treatment of the cleavage product only about two mols of carbonic acid are evolved in the course of six hours without the formation of carbonic acid being completed In contrast to the lactoflavin *d* we can extract with ether from the oxidation products of the pigments soluble in chloroform a substance which corresponds completely to the Lyochromes with respect to its colour and fluorescence but in which nitrogen can no longer be demonstrated by the test of Lassaigne The search for the constitution of the Lyochromes must start with such decomposition products

An important property of the Lyochromes which must be expressed in the constitutional formulæ is the reversible reduction to a leuco substance These leuco substances are formed for example by a biological process if whey is left standing for some time so that it becomes covered with a film of microbes The liquid under this film does not show the Lyochrome fluorescence but the fluorescence can be restored immediately by shaking it with air Chemically the leuco substances can be obtained by reduction with hydrosulphite with hydrogen sulphide in a weakly alkaline solution and also with titanous chloride Of other chemical properties of the Lyochromes in the first place their great stability to oxidising agents must be mentioned The Lyochromes are not attacked by concentrated nitric acid bromine water or hydrogen peroxide Hydrogen peroxide in presence of iron salts and cold permanganate attacks them only slowly but they are very quickly destroyed by hot permanganate

Hitherto the existence of Lyochromes has been determined by ourselves in animal organs in whey and in urine The wide distribution of this new group of natural pigments is further evident from the papers of Warburg and Christian and also of Kuhn Gyorgyi and Wagner Jauregg These investigators detected yellow green fluorescent pigments of Lyochrome character in yeast in very high concentration in cultures of the lactic acid bacterium in muscle in white of egg and also in vegetable materials Warburg and Christian found in the course of their search for the so called second respiratory ferment pigments of Lyochrome character and they were able to show that the combination of a yellow green fluorescent pigment with a carrier of high molecular weight represents this iron free respiratory ferment itself This respiratory ferment is therefore not dialysable in contrast to the Lyochromes of whey We have found that in contrast to that of cow s milk the pigment of human milk is also fixed on a carrier probably on albumin Lastly Kuhn Gyorgyi and Wagner Jauregg have been led to this new sphere of pigment investigation by researches directed to the isolation of the vitamin B_2 Vitamin B_2 appears to belong to the Lyochromes To this statement we must make the reservation that the crystallised Lyochrome which in the opinion of these investigators are the cause of the vitamin effect require for the production of their effect on growth to be supplemented by a substance chemically not yet defined (vitamin B_4) The crystallised pigments which Kuhn Gyorgyi and Wagner Jauregg were able to isolate first from white of egg and then from whey are similar or identical with the lactoflavin *d* isolated by ourselves from whey The possibility cannot be denied that the different natural Lyochromes may consist of the same pigment component united with different other substances acting as carriers

We find accordingly in whey Lyochromes of very different molecular dimensions Including the substances obtained by decomposition of the original Lyochromes we can at present construct the following series arranged in order of molecular dimensions

(1) The pigments united to a non dialysable carrier (albumin ?) from human milk corresponding to the second respiratory ferment of Warburg and Christian

(2) The pigments in combination with purin substances (lactoflavins *a–c*)

(3) A single pigment (lactoflavin *d*) corresponding to the ovoflavin and the lactoflavin of Kuhn Gyorgyi and Wagner-Jauregg

(4) The photochemical cleavage product that

is, the pigment without H_2O (water) and $C_3H_4O_4$ (malonic acid ?), corresponding to the cleavage product from yeast of Warburg and Christian

(5) The oxidation product of the photochemical cleavage product, soluble in ether (free from nitrogen ?)

Warburg and Christian have described the evolution of urea from their photochemical cleavage product by treatment with alkali, by which means the remaining substance, $C_8H_{10}O_2N_2$, loses its whole power of fluorescence and all but a small remnant of its colour It must be accepted that in this treatment an intramolecular transformation of the remaining substance also takes place , for our probably nitrogen free oxidation product, obtained from the product of photochemical cleavage, still possesses fluorescence and colour to such an extent that the nitrogen content is very unlikely to have any connexion with these properties

The three starting points of the researches leading to the discovery of the new group of animal pigments—namely, the functions of the liver and the kidney, the respiratory ferment, and the action of vitamin B_2—together indicate the great physiological importance of this new class of pigments While the function of the Lyochromes as respiratory ferment is completely explained, their character as vitamin B_2 still requires further investigation, since in the researches so far made their effect as vitamin B_2 was evident only with the addition of chemically unknown substances The physiological significance of the occurrence of Lyochrome in the kidney and the liver is still quite unknown On the respiration of normal tissue cells Lyochromes have no effect, as we ourselves, and also Wagner Jauregg and Ruska[8], have observed On the other hand, Stern and Greville[9] found that mammalian red blood corpuscles, which have practically no intrinsic respiratory activity show a significant increase of oxidation in the presence of Lyochrome It is very probable, however, that the substances used in these experiments as Lyochromes were not of that character , for, according to the investigations of one of us on the Lyochromes of the urine, the Urochrome used by Stern and Greville for their respiration experiments has no Lyochrome properties

To summarise The Lyochromes are characterised by the following qualities (1) solubility in water , (2) red to orange colour of the crystals, and orange to yellow colour of their watery solutions , (3) yellow green fluorescence , (4) extinction of this fluorescence by acid and alkaline reactions , (5) reversible reduction to leuco substances , (6) stability against oxidising agents

The chemical investigation of the group, in spite of the small concentration of the Lyochromes in organic materials, has already advanced so far that in the near future we may expect that their chemical structure will be revealed, and that a knowledge of new relations between chemical constitution and physiological action will be afforded thereby

---

[1] The method of intravital microscopy has been described by Ph Ellinger and A Hirt in the *Zeitschrift für Anatomie und Entwicklungsgeschichte*, vol 90 p 791 1929 and in Abderhaldens Handbuch der biologischen Arbeitsmethoden vol 5 11, p 1753 1930 It permits living animal organs to be examined with the strongest microscopical magnifications by injecting the animal with fluorescent dyestuffs With ultra violet illumination these dyes provide by fluorescence in the cells themselves the light required for visible illumination of the microscopical picture

[2] Bleyer and Callmann *Biochem Z* 155 54 1925

[3] O Gerngross and M Schulz *Milchwirtschaftliche Forschung* 6 567 1928

[4] Details of this procedure as well as of further chemical operations are described in our publications Ph Ellinger and W Koschara *Berichte der Deutschen Chemischen Gesellschaft* 66 315 808 1411 , 1933

[5] We had made an agreement with R Kuhn, P György and Th Wagner Jauregg who worked over the same field and who called their substances Flavins , to call the whole group Lyochromes and their single specimens Flavins with the addition of the names of the materials of origin so that the Flavin from milk is called Lactoflavin

Obituary

Prof F Ll Griffith

FRANCIS LLEWELLYN GRIFFITH, whose death at the age of seventy one years occurred on March 14, was, like a number of other distinguished Englishmen, the son of a clergyman, the Rev John Griffith, who was for many years rector of Sandridge, Herts, and a mathematician of some repute After being educated at Brighton College, Sedbergh and Highgate, he came up to Oxford as a scholar of Queen's College, where, under the influence of Prof A H Sayce, he began those studies which were destined to win him later a world-wide fame He took his B A degree in 1884, and during the winter seasons of that and the three following years he was engaged in excavation and other research work in Egypt under the leadership of Petrie and Naville For some months of the season 1886–87 he was busy copying the inscriptions in the tombs of the First Intermediate Period and Middle Kingdom at Asyût and Dêr Rîfeh His publication of these texts ("The Inscriptions of Asyût and Dêr Rîfeh", 1889) not only shows that even at this early date he had acquired a sound knowledge of Middle Egyptian, but already displays that scholarliness and meticulous accuracy which are so characteristic of all his subsequent work

From 1888 until 1896, Griffith was an assistant in the Department of British and Mediæval Antiquities in the British Museum In 1892 he was made assistant professor of Egyptology at University College, London, a post which he retained until he was appointed reader of Egyptology at Oxford in 1901 During those years his output was remarkable both for quantity and quality, its crowning achievement being the publication in two volumes of Petrie s great find of papyri at Kahun and Gurob Most of these are documents written in the cursive business hieratic of the Middle Kingdom, a script of which there had hitherto been found few, if any, examples In his mastery of this difficult script and in his interpretation of the contents of the documents, Griffith showed that he possessed that rare gift—real genius Many years have passed since those two volumes appeared, and there has been a great advance in our knowledge of Middle Egyptian grammar and syntax, but even so, Griffith's translations and transcriptions need comparatively few corrections

For the next ten years or so Griffith devoted himself primarily to the study of Demotic, and by the end of that period was the foremost Demotic scholar in the world His ' Stories of the High Priests of Memphis" (1900) the Demotic Magical Papyrus of London and Leyden , which he produced in collaboration with Sir Herbert Thompson (1907–9), and above all his Catalogue of the Demotic Papyri in the Rylands Library (1909) placed Demotic studies on a new footing and gave them an interest which, in the minds of some of us at any rate, they had hitherto seemed to lack

About the year 1907, Griffith found opportunity for winning laurels in a new field Excavations in the Sudan and Lower Nubia were producing inscriptions in the Meroitic script hitherto undeciphered, and the finders handed them over to him to investigate After a few years of intensive study, he could decipher the script and had advanced far towards a complete understanding of the language

In due course Griffith turned back to Demotic and was actually engaged at the time of his death in the publication of the Demotic inscriptions occurring in the temple of Philae and in the temples of Lower Nubia, a great and most important undertaking

In the winter season 1910–11, Griffith and his wife conducted excavations on behalf of the University of Oxford in Lower Nubia, and they continued these activities until the winter season 1913–14 In 1922 and 1923 they excavated for the Egypt Exploration Society at El Amarna Twice since then they have excavated in the Sudan, the site of their last campaign (1930–31) being Kawa, where they unearthed three temples, one of which had been founded by Tirhaqa At Kawa, beside several large stelæ bearing inscriptions of great historical interest, they found a number of reliefs and statues and a quantity of other antiquities, some being of considerable artistic merit

In 1924, in consideration of his services to Egyptology and to the University of Oxford, Griffith was given the status of professor, and, though he resigned the chair in 1932, he acted as deputy professor until the late Prof Peet was transferred from the University of Liverpool to succeed him in October 1933 Griffith was a D Litt of Oxford, an honorary fellow of Queen's College, a fellow of the British Academy and also of the Society of Antiquaries, an honorary LL D of the University of Aberdeen and an honorary D Phil. of the University of Leipzig He was a corresponding member of the Royal Academy of Sciences at Berlin, and a foreign associate or corresponding member of many other famous learned societies in Europe

He was twice married, and his second wife, who has rendered him notable assistance in his excavations in Egypt, Lower Nubia and the Sudan and in the production of many of his publications survives him

Griffith was a man of wide interests Beside a profound knowledge of Egyptology in all its branches he was well acquainted with the archæology of his own country and of foreign countries other than Egypt He was very fond of music and was a good naturalist and botanist He was a delightful companion for a country walk pointing out and discussing any interesting flower or plant that he observed growing in hedgerow or field and he knew every bird by its notes It should here be stated that his great knowledge of the birds fish and other animals of Egypt is made manifest in many of his books and articles A charming trait in his character was his love of children, who found in him an ideal companion He would take them round his garden and talk to them about the birds and plants and the creatures living in stream or pond Small children, frightened of strangers in general, took to him immediately and, when next he appeared on the scene, welcomed him with open arms

His was a full life and he accomplished much He died, as all would wish to die, in full possession of all his faculties and with his mind occupied to the last in the work he loved

ALYWARD M BLACKMAN

DR H S WASHINGTON

WITH the death of Dr Henry Stephens Washington on January 7 at the age of sixty six years, petrology has suffered the loss of one who, for the past forty years, has worked with distinction and has contributed greatly to the advancement of the science

Henry Stephens Washington was born at Newark, New Jersey, on January 15, 1867, and, after due preparation, he proceeded to Yale where he obtained, in 1886, the degree of B A with special honours in natural sciences After two years of post graduate work he graduated M A in 1888 The next four years were spent in travelling in the West Indies, Europe, Egypt, Algeria and Asia Minor, parts of the four winters and springs being spent in Greece where he became a member of the American School of Classical Studies In the latter capacity he assisted in and conducted excavations at Plateae, Argos and Phlius

Between 1891 and 1893 Washington studied petrology under Zirkel at the University of Leipzig and obtained his doctorate with a thesis on 'The Volcanoes of the Kula Basin in Lydia After wards he was assistant in mineralogy at Yale for a short time and continued his petrographical researches in Europe and America From 1906 until 1912 he practised as a consulting mining geologist and in 1912 he was appointed petrologist to the Geophysical Laboratory in Washington a position which he still held at the time of his death

Dr Washington travelled extensively and the results of his geological petrological and volcanic studies in Europe North America Brazil Asia Minor and the Hawaiian Islands are incorporated in numerous publications His devotion to the chemical side of petrology was the ruling factor in his career and his skill as an analytical chemist and petrographer together with an unfailing interest in volcanic processes and rocks have contributed greatly to our present knowledge of modern lavas At the same time his scientific activities embraced a much wider field and his investigations ranged from archæological subjects to problems of the earth's interior

In 1904 he published his Manual of the Chemical Analysis of Igneous Rocks the fourth edition of which appeared in 1930 He was joint author with Cross Iddings and Pirsson of The Quantitative Classification of Igneous Rocks published in 1903 and author of the Chemical Analyses of Igneous Rocks which was issued by the United States Geological Survey as a Professional Paper in 1903 and in an enlarged edition in 1917 An enormous amount of work is represented in this compilation of which the importance from a petrological point of view cannot be over estimated it must always remain an admirable memorial to its author

It is impossible to deal adequately with Washington's scientific publications which form an imposing list but among the more important may be mentioned The Roman Co Magmatic Region (1906) The Deccan Traps and other Plateau Basalts (1922) 'The Petrology of the Hawaiian Islands (1923–1928) and The Composition of the Earth's Crust (1924 in collaboration with Dr F W Clarke)

Dr Washington's scientific attainments were widely recognised both in the United States and in Europe He was a foreign member of the Geological and Mineralogical Societies of London of the Paris Academy of Sciences and of the Academies of Science of Norway Turin and Modena and of the Royal National Academy of the Lincei (Rome)

With his death geology must mourn the passing of a great figure in the petrological world

We regret to announce the following deaths

Prof J R Ainsworth Davies formerly principal of the Royal Agricultural College Cirencester on April 7 aged seventy two years

Prof A B Macallum F R S formerly professor of biochemistry in the University of Toronto lately professor of biochemistry in McGill University on April 5 aged seventy four years

Sir Frederick Palmer K C M G C I E president of the Institution of Civil Engineers in 1926 27 who was a well known bridge and harbour engineer on April 7 aged seventy two years

Prof Sydney H Vines F R S formerly Sherardian professor of botany in the University of Oxford president of the Linnean Society of London in 1900–4 on April 4 aged eighty four years

News and Views

Letters to the Editor

An explanation is due to our readers for the unusually large proportion of this week's issue of Nature devoted to Letters to the Editor In Nature of February 10 we published an enlarged paper to provide accommodation for twenty columns of correspondence since then we have printed a dozen or so letters each week which have occupied altogether a hundred columns of space In fairness to our correspondents it should be said that many of them have acted upon our suggestion that communications should be reduced in length but still it has been difficult to ensure that prompt publication of current work which is now so widely recognised as one of the chief functions of our correspondence columns In the circumstances it has been decided once more to publish an extra number of pages of correspondence in order to reduce the waiting list and the present issue of Nature therefore contains thirty two columns under the heading Letters to the Editor Of the twenty nine communications printed about a half are from centres in Great Britain and Ireland The remainder come from places so wide spread as Copenhagen Leningrad Moscow and Warsaw in Europe Boulder Chicago Harvard and Montreal in North America Sendai in Japan Cairo and Kyancutta (South Australia) They provide further evidence if such be needed of the wide circulation of this journal and the keen activity with which scientific problems are being attacked in many parts of the world

Prof G H Lemaître

Prof G H Lemaître professor of mathematical methodology and the history of mathematical sciences in the University of Louvain has been awarded the Francqui Prize of the value of 500 000 francs The Francqui Foundation was created in 1932 and may award this annual prize to the Belgian who has made outstanding contributions to science and thus enhanced the international prestige of Belgium. This year's prize has been awarded to Prof. Lemaître for his outstanding work on the systems of galaxies and on cosmic theory. His discoveries and theories have had a profound influence on astrophysical and physical thought throughout the world, especially in connexion with the theory of the expanding universe which he originated. The presentation was made in the presence of the King of the Belgians.

Native Problems in North Australia

THE natives of Arnhem Land in North Australia are presenting an interesting problem to the Commonwealth Government. The methods usually adopted in dealing with disturbances among the natives are the old time punitive police expedition or special missionary enterprise; quite recently a mixture of the two has been tried. As Prof. F. Wood Jones has pointed out, the former is apt to lead merely to massacre and the latter must be admitted to have failed to effect any permanent solution of the problem. It is properly soluble only by rigorous segregation of the blacks from settlers, traders and the like (European and Asiatic), and by prolonged intimate study of them by highly trained anthropologists willing and able to live amongst them as members of their tribes. The University of Melbourne has made an admirable and practical move in offering to the Department of the Interior the services of an able and experienced research student to work amongst the Arnhem Land natives. To the great regret of all who are interested in these primitive peoples, the offer has been declined, but the last has not been heard of it. On scientific no less than humanitarian grounds a determined effort along sound modern lines should be made to resolve this long neglected native problem. The establishment of a Commonwealth Department of Native Affairs would be a step in the right direction.

Water Supplies in Great Britain

IN reply to a question in the House of Commons on April 9 as to the present position in regard to water supplies in Great Britain, Mr. Ramsay MacDonald said: "The reserves of many water undertakers have fallen to a low level for this time of the year. The Government have been carefully watching the situation and, because of the continued absence of abundant rains, are satisfied that emergency measures must be taken. Therefore, in view of seriousness of the position, the Government propose to bring legislation before the House immediately." The Water Supplies (Exceptional Shortage Orders) Bill was accordingly presented to the House on April 10, whereby the Minister of Health, and the Secretary of State and the Department of Health for Scotland, would be authorised "to make orders, and to give directions with a view to meeting deficiencies in water supplies due to exceptional shortage of rain, and for purposes connected with the matters aforesaid". It will be remembered that the subject of water supply and regulation was discussed in NATURE of November 11, 1933, p. 725, in an article dealing with a report of a committee of the British Association when the institution of an inland water survey of Britain was urged as a necessary preliminary to efficient water administration. Reference was also made in that article to the presidential address to the Institution of Mechanical Engineers delivered by Mr. Alan Chorlton, M.P., in which he suggested the construction of a water grid in Great Britain comparable with the electricity grid recently completed.

Pooling of Water Supplies

MR. CHORLTON returned to the subject in a recent paper read before the Royal Society of Arts (*J. Roy. Soc. Arts*, Feb. 23, 1934), in which he directs attention to the policy of Great Britain which has allowed water supply to remain in the hands of local authorities without any national plan devised in the interests of the population as a whole. As a result there are 1,100 separate water undertakings in the country with a mosaic of disconnected entities and interlocking boundaries. Urban areas are best served, but many rural areas require adequate provision. A hydrogeological survey is needed before plans on a large scale can be matured. Furthermore, some pooling of supplies is essential because of the vagaries of rainfall within any given year, and lastly, special storage reservoirs should be constructed to serve abnormal demands in dry seasons. These might be in the Thames valley for the south generally, in south Lincolnshire for the Ouse flood waters, and in the Lake District to serve the industrial areas of Lancashire. Such undertakings would, according to Mr. Chorlton, have many advantages in providing a certainty of good water in all areas and a possibility of encouraging increased use of water without alarm of shortage, while the expenditure on labour would decrease unemployment for some years to come.

Australian Support for Empire Agricultural Research

SATISFACTION will be felt at the decision of the Commonwealth Government to adopt the recommendation of the Executive Council of the Imperial Agricultural Bureaux that financial support be given to certain research organisations in Great Britain formerly assisted in part by the Empire Marketing Board. It is true that the sum involved is not very considerable—£800 per annum to the Entomological Laboratory at Farnham Royal, £500 to the Station at Slough dealing with insect infestation of stored products, and £4,500 to the Low Temperature Research Station at Cambridge—a total of £5,800 per annum. The point of importance, however, is that the Australian decision is an indication of the growing feeling there that teamwork in agricultural research is not merely desirable in the interests of the various members of the Empire, but also is essential if full advantage is to be taken of the limited total resources available for scientific work. The Empire Marketing Board did much to foster this spirit, the value of which is clearly recognised in the outlying dominions

Rothamsted Experimental Station

THE recent appeal for £30,000 for the purchase of the Rothamsted experimental fields has met with a ready response and already £22,000 has been promised This is due chiefly to the generosity of Mr Robert McDougall of Cheadle, who has offered £15,000, and the Sir Halley Stewart Trust, which has offered £5,000, on condition that the remaining £10,000 be secured by May 12, when the option on the land expires Towards this, £1,000 has already been given by Sir Bernard Greenwell, and another £1,000 by other donors Strenuous efforts are now being made to obtain the remaining £8,000 and all friends of Rothamsted are invited to send subscriptions to the Director, Rothamsted Experimental Station, Harpenden Barclays Bank and the National Provincial Bank have kindly posted the appeal in their rural branches and the National Farmers' Union is asking its branches to help But the countryside though sympathetic and appreciative, is not well off, and for much of the £8,000 the Station will have to depend on the generous help of public spirited men and women who, while recognising the importance of agriculture to the community, are not themselves actually farming It would be indeed a tragedy if Rothamsted should, after all, lose these fields now that success seems so nearly within reach

Short Wave Radio Echoes

IT is now well known that all long distance radio communication takes place by means of electric waves reflected from one of the ionised regions of the atmosphere, the time of travel of the waves from the emitting station up to the reflecting layer and back to the earth being usually a small fraction of a second Some six years ago a Norwegian engineer, G Hals, discovered the existence at certain times on short wave lengths of wireless echoes received as long as three seconds after the cessation of the original signals (see NATURE, 122, 681, Nov 3, 1928) These observations were afterwards confirmed by Prof C Størmer, and specially organised experiments by experts in different countries showed that echoes of up to 25 or 30 seconds' delay could be detected, although they were of rather rare and uncertain occurrence

To explain the existence of such echoes, Prof Størmer put forward the suggestion that the emitted waves had penetrated the ionosphere and were reflected from a belt of electrified corpuscles ejected by the sun and formed into a vast toroid by the influence of the earth's magnetic field If the waves travelled with their normal velocity, this toroid would have to be situated at a distance of several hundred thousand miles from the earth Other investigators, however, pointed out that the variation of the group velocity of the waves in the ionosphere might be an important consideration in defining the actual path of the waves In order to obtain more experimental data on this subject, Prof E V Appleton, of King's College, London, who is well known for his investigations of the ionosphere, has suggested that observations should be carried out by a large body of amateur listeners equipped with suitable short wave receivers The formation of an organisation suitable for this and other similar investigations is described in *World Radio* of April 6 by Mr Ralph Stranger, of the technical staff of that journal It is proposed that a number of powerful transmitting stations in Great Britain and other countries should emit at certain times strong characteristic signals, which will be the subject of observation throughout the world The results obtained will be collected and carefully analysed The conclusions reached from the conduct of this large scale experiment will be awaited with interest

Centenary of the Royal Statistical Society

THE ROYAL STATISTICAL SOCIETY had its birth at a meeting held in London on March 15, 1834, under the chairmanship of the Marquis of Lansdowne, and the centenary will be celebrated on April 17, when the Prince of Wales, an honorary president of the Society, will preside at a meeting to be held at University College, London The Society arose out of the Cambridge meeting in 1833 of the British Association During the meeting which was attended by the famous Belgian mathematician, Quételet, a small gathering of members interested in statistics was held in Trinity College Through this, Babbage was led to suggest the formation of a statistical section of the Association His suggestion was approved and a committee appointed It was, however, soon recognised that for the collection of materials a more permanent society would be required, and this led to the meeting of March 15, 1834, when it was resolved to establish a Statistical Society of London (see NATURE, March 10, p 389) The Society was incorporated in 1887, and is now in a flourishing condition One of the original recommendations was that it should of course be one prominent object of the Society to form a complete Statistical Library as rapidly as its funds may admit ' The Society has now a library of more than sixty thousand volumes

Local Government Officers

IMPORTANT recommendations regarding the qualifications, recruitment, training and promotion of local government officers are made in the recent report of a departmental committee under the chairmanship of Sir Henry Hadow to the Ministry of Health (London H M Stationery Office 1*s* 6*d* net) The Committee considers that considerable revision of the present system of recruiting and training officers is necessary, and makes the principal recommendation that a permanent central advisory committee should be appointed, representative of local authorities, to investigate and advise in all questions affecting local government service The co operation of such a central body is necessary to give effect to the Committee's proposals with regard to entry to the service by competitive examinations, the recruitment of an increased number of university graduates, on which special stress is laid, and the investigation of conditions of training, particularly with respect to the establishment of an administrative examination of appropriate standard for passing from the general grade of clerical officers to the higher grades

OTHER recommendations relate to the adoption of uniform grading systems and salary scales, the wide notification of vacancies, the establishment of a minimum age limit of sixteen years, coupled with the possession of a school certificate for entry to the service A certain proportion of junior clerical officers should be recruited at eighteen or nineteen years of age, apart from the systematic recruitment of university graduates and of professional and technical officers from all available sources A thorough investigation of technical qualifications is required, and coupled with greater precautions against personal influence in making appointments, greater mobility of officers between local authorities, the assignment by each local authority to one establishment committee of all questions affecting the recruitment, qualification, training and promotion of officers, these suggestions should assist in the development of a local government service able to meet the increasingly onerous demands made upon it

New Cheshire Nature Reserves

THE two Nature reserves in memory of the late T A Coward, the well known naturalist and author of The Birds of Cheshire" and The Vertebrate Fauna of Cheshire", of the Manchester Museum, who died on January 29, 1933, have been completed in Cheshire They have been formed by a committee of naturalists and admirers, the T A Coward Memorial Fund, under the chairmanship of the Right Hon the Earl of Stamford, though as yet some £200 of the purchase money is required It is proposed to hand the reserves over to the care of some national body like the National Trust The two sites chosen were Marbury Mere in mid Cheshire, and Cotterrill's Clough, a hanging' wood on the banks of the River Bollin within sight of Coward's home at Bowdon (NATURE, 132, 437, Sept 16, 1933) Each locality is rich in bird life At the latter, Coward recorded the grasshopper warbler, and used it for the recording of the arrival of migrant species, while the former, which includes a large lake and 1½ acres of woodland, and large reed beds which bring the extent up to 8 acres, is where the black tern, bittern, night heron, whooper swan, Bewick's swan, and great crested grebe have been recorded Some recent Marbury records include the white wagtail, a drake and two duck wigeon in July, scaup duck, goosander, cormorant, great northern diver, and ringed plover (Nineteenth Annual Report, Lancashire and Cheshire Fauna Committee) The honorary secretary of the Coward Memorial Fund is Mr J F. Hodkinson, 50 Selby Street, Manchester, 11

Roman Scotland

SIR GEORGE MACDONALD's reconstruction of the history of the Roman wall from Forth to Clyde, and of the strategic position in Roman Scotland in the second century A D from the evidence of his excavations, which appeared in the *Times* of April 7, justifies his citation of the dictum of the late Prof Haverfield that the spade would prove mightier than the pen, but at the same time will suggest to his readers the qualification that its superiority depends upon the skill of the excavator, and his constructive powers in the interpretation of his finds Sir George's ability in this respect enables him to piece together the data he has obtained from the thirty seven miles of wall between Bridgeness on the Forth to Old Kilpatrick on the Clyde, with its forts, ditch and flanking road for supply purposes, and to supply from it a conclusive solution for the more puzzling problems of a political and military situation which required the building of the forward line of defence and yet at the same time did not relieve the garrison of Hadrian's wall to the south The key to the situation, which he now supplies, is the vulnerability of the intra mural area from the inroads of the Dalriada Scots of Ireland through Galloway Further, he suggests, the country north of York being occupied in a military sense only, even though the outer wall provided an efficient barrier against attack by the northern tribes, it was necessary to have a garrison on the southern wall to shut off the partially subdued tribes on the southern side of the wall from those in the occupied Scottish area, in order to prevent any junction of disaffected tribesmen Sir George's suggestion that shortage of man power and a miscalculation of the pressure which could be brought to bear by Irish inroads is a logical, but none the less brilliant, reading of the situation when about 185 A D the outer line of defence was abandoned

An Expedition to Hainan

ALTHOUGH the flowering plants of Hainan have been extensively collected by Prof Woon Young Chun and his associates of the Botanical Institute, National Sun Yatsen University, Canton, the animals of the island, although previously collected by a few naturalists, are still incompletely known to the scientific world The Fan Memorial Institute of Biology, the Biological Laboratory of the Science Society of China, the Metropolitan Museum of Natural History of the Academia Sinica, the National Tsing Hua University, the National University of Peking, the National Shantung University and Nankai University have recently organised a joint expedition to Hainan The purpose of this is to collect zoological specimens as extensively as possible Cryptogams, orchids and wood samples will also be collected The Fan Memorial Institute of Biology will be represented by C Ho, entomologist, and S K Tang, taxidermist, the Biological Laboratory of the Science Society of China by Dr C C Wang, invertebrate zoologist, and Mr K F Wang, ichthyologist, the Metropolitan Museum of Natural History by Dr. H W Wu, ichthyologist, the National Shantung University by Mr C L Tso, botanist, and Mr Chungin H Liu, anthropologist, and Nankai University by Dr T S Hsiung, invertebrate zoologist Mr. C L Tso, who has had previous experience in the island and is familiar with the natives, will lead the expedition The members of the expedition were to leave Shanghai about January 15. One party is going to the famous Wu tchi shan or Five Fingers Mountain As the mountain attains the height of more than 2 000 metres zoological specimens, especially land vertebrates will be thoroughly collected in order to study the problem of vertical distribution Another party will make a coastal survey and pay more attention to the sea fauna

Research and Industry in New Zealand

NEW ZEALAND's position in relation to world commerce was reviewed by the Governor General Lord Bledisloe on September 29 in an address to the Canterbury Chamber of Commerce at Christchurch In the course of the address he referred to the resentment often expressed in regard to excessive mechanisation and other social and economic ills entailed by the progress of scientific research and the application to industrial processes of the resulting discoveries The remedy is to be sought he suggested not in arresting the march of science especially in a country which has so much to gain from agricultural and other scientific research but rather in redoubling research in those fields of economics psychology sociology and education in which are to be sought solutions of those problems which have hitherto baffled mankind of the distribution of the wealth which the applications of other branches of science have already made abundantly accessible From the enunciation of this doctrine of the social centrality of present day science he passed on to consider the limits within and conditions on which State guidance and organisation are likely to produce better results than unshackled individual enterprise

'Discovery' Report on Foraminifera of South Georgia

A CORRESPONDENT Mr M E Challen has directed our attention to the fact that in Mr A Earland's report on the Foraminifera of South Georgia (Discovery Reports 7 27 138 1933) a new species (No 158) *Bigenerina minutissima* is recorded from two stations WS 199 WS 472 not included in the chart Mr Earland informs us that the species in question was not found in the South Georgia area and that its inclusion was an error observed too late for correction in proof The two stations WS 199 WS 472 are in the deep water of the Scotia Sea within the area covered by his forthcoming report on Antarctic Foraminifera References to them have also crept into the South Georgia report under *Ammobaculites agglutinans* (No 116) *Ammomarginulina ensis* (No 122) and *Clavulina communis* (No 165) but are of less importance as these species were found elsewhere in the South Georgia area Protozoologists may be glad to rectify these errors in their copies of the report

Prof S H Vines, F R S

OUR Oxford correspondent writes The tenure of the Sherardian professorship of botany by the late Sydney Howard Vines F R S which lasted from 1888 until 1919 was marked by a notable development in the activity and usefulness of the botanical department of the University The studies of this department associated in former years with the names of Morison Sherard Dillenius Sibthorp and Daubeny to which a quickening stimulus had already been applied by the vigorous personality of Sir Isaac Bayley Balfour were by Prof Vines advanced to a high degree of efficiency and the results of the energy which he brought to bear on the duties of his office are still apparent in the flourishing condition of the department of which Prof A G Tansley F R S is the present head The memory of Vines will live in Oxford as that of one whose outstanding ability and social charm made a deep and enduring impression on all his contemporaries

Aberdeen Public Library

ARRANGEMENTS in connexion with the meetings of the British Association in Aberdeen in September are in an advanced state It happens that the jubilee of Aberdeen Public Library—established 1884—occurs this year and the Library Committee proposed to celebrate the anniversary by offering the hospitality of the Library to representative members of the British Association, mainly in the form of an evening reception in the Central Library It happens however that no evening is available in the Association's programme Accordingly the celebration is to take the form of a luncheon in the Reference Department of the Central Library on Friday September 7

New Committee for Research in Mental Disorders

THE Medical Research Council in consultation with the Board of Control has appointed a new committee to advise and assist in the promotion of research into mental disorders The reconstituted committee will include representatives not only of psychiatry medical psychology and the study of mental deficiency but also of neurology physiology biochemistry pathology and genetics The chairman of the Committee will be Prof E D Adrian of the Medical Research Council and the following will also serve Sir C Hubert Bond Board of Control Dr Bernard Hart University College Hospital London Prof D K Henderson Royal Edinburgh Hospital for Mental and Nervous Disorders Dr T A Ross Cassel Hospital Penshurst Dr E O Lewis Board of Control Dr C P Symonds Guy's Hospital London Dr J H Quastel Cardiff City Mental Hospital Dr J G Greenfield National Hospital for Nervous Diseases London F L Golla Maudsley Hospital London, and Dr L S Penrose Royal Eastern Counties Institution Colchester Sir David Munro of the Council's staff will act as secretary

Research Conference on Spectroscopy and its Applications

ON account of the enthusiastic response to the Spectroscopy Conference held at the Massachusetts Institute of Technology last summer which was attended by more than a hundred workers from America and abroad it has been decided by the Institute to hold a second conference this year A programme of papers and discussions is being prepared on the following topics among others absorption spectrophotometry (application to analysis of *organic and inorganic substances and to the diagnosis* and treatment of disease) analysis by the emission spectrum (determination of metallic and other atomic and molecular constituents of samples) biological and chemical effects of spectral radiation spectroscopy of the ultra violet and infra red analysis of spectra and measurement of wave length It is anticipated that the earlier sessions of the week will be of especial interest to biologists medical research workers and chemists The main emphasis will then shift to subjects of chief interest to the industrialist and engineer the geologist and the metallurgist The latter part of the week will be devoted to more theoretical problems of the spectroscopist The meetings will be open to anyone interested in the topics under discussion The Massachusetts Institute also announces a special programme of summer courses on spectroscopy and its applications to be given during the six weeks preceding the conference which will deal primarily with applications of spectroscopy to biology chemistry geology metallurgy and mineralogy Inquiries regarding the Conference and courses should be addressed to Prof G R Harrison Department of Physics Massachusetts Institute of Technology Cambridge Massachusetts

Announcements

THE Garton Prize of £500 and Gold Medal of the British Empire Cancer Campaign offered this year for an essay on The Biological Effects and Mode of Action of Radiations upon Malignant and other Cells has been awarded to Dr H A Colwell of Middlesex Hospital London As one of the other essays was of high merit the Grand Council of the Campaign has decided that a second award of £100 should be made to its authors Dr F G Spear in association with Dr R G Canti Mr I G Grimmett Dr B Holmes Miss S F Cox and Dr W H Love

THE HON OLIVER STANLEY M P Minister of Transport will unveil a tablet erected at University College London by the executive committee of the Trevithick Centenary Commemoration on April 23 The tablet commemorates Trevithick s locomotive experiments in 1808

PROF E K RIDEAL professor of colloid science in the University of Cambridge will deliver the twenty fourth annual May Lecture of the Institute of Metals on May 9 at the house of the Institution of Mechanical Engineers taking as his subject Gases and Metal Surfaces

THE Annual Congress of the South Eastern Union of Scientific Societies will be held at the University of Reading on July 11–14 Further information can be obtained from the Hon General Secretary, Mr Edward A Martin 14 High View Close Norwood London S E 19

A TOUR of Norway (Oslo and Bergen areas) has been arranged by the Geologists Association to take place on August 2 14 Further information can be *obtained from the Secretary Mr W L Turner* 18 Valley Road Shortlands Bromley Kent

PROF F A F Crew director of the Institute of Animal Genetics University of Edinburgh has received the following telegram from Prof N I Vavilov All Union Soviet Conference at the Academy of Science Leningrad on the Evolution of Domestic Animals express greatest regret on the death of Professor Cossar Ewart pioneer of investigations on the origin of domestic animals President of Conference Vavilov

A COURSE of lectures on Pathological Research *in its Relation to Medicine* will be *given in* the lecture theatre of the Bacteriological Department of the Institute of Pathology and Research St Mary s Hospital London W 2 on Thursdays at 5 p m commencing on April 12 Sir Almroth Wright principal of the Institute is giving the opening lecture The other lecturers will be Prof A Bethe H W Bell Cairns Sir Bernard Spilsbury Prof J B S Haldane Prof J C Drummond Prof E N da C Andrade Dr Leonard Colebrook

A COURSE of two lectures delivered by Dr A N Whitehead before the University of Chicago last October will be published shortly by the Cambridge University Press under the title Nature and Life The book is an attempt in brief to unite the world of science with the worlds of religion art literature and morality and to show that Nature itself has processes goals beauty and values

APPLICATIONS are invited for the following appointments on or before the dates mentioned —A head of the Textile Department at the Municipal Technical College Halifax—The Principal (April 20) A chemist for the Aeronautical Inspection Directorate Air Ministry Test House Kidbrooke S E —The Secretary S 2 Air Ministry Kingsway W C 2 (April 21) Two economists for the Ministry of Agriculture and Fisheries The Secretary Ministry of Agriculture and Fisheries 10 Whitehall Place London S W 1 (April 23) An assistant lecturer in chemistry (subsidiary botany or pharmacognosy or pharmacy) at the Belfast Municipal College of Technology—The Principal (April 24) Two chemists (Class II) *male* in the Department of War Department Chemist—The Under Secretary of State The War Office (C 5) London S W 1 (April 28) An assistant lecturer in geography at the University of Manchester—The Registrar (April 30) Examiners in anatomy and physiology for the fellowship and in biology anatomy, physiology etc for the Conjoint Board at the Royal College of Surgeons of England—The Secretary (May 1) An assistant lecturer in dietetics and physiology at the King s College of Household and Social Science Campden Hill Road London W 8—The Secretary (May 5)

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of rejected manuscripts intended for this or any other part of Nature *No notice is taken of anonymous communications]*

Disintegration of the Diplon

It has been shown by Oliphant Harteck and Lord Rutherford in a recent letter[1] that the bombardment by high velocity diplons of compounds containing diplogen gives rise to three groups of particles two groups of equal numbers of singly charged particles of ranges 14 3 cm and 1 6 cm together with neutrons of maximum energy of about three million volts They suggest as possible explanations of these results the reactions

$$ _1D^2 + {}_1D^2 \rightarrow {}_1H^1 + {}_1H^3 \qquad (1)$$
$$\text{and } {}_1D^2 + {}_1D^2 \rightarrow {}_2He^3 + {}_0n^1 \qquad (2)$$

an atom of $_1H^3$ of 1 6 cm range and a proton of 14 3 cm range satisfying the momentum relations in reaction (1) In this reaction it is to be expected that the proton and the isotope of hydrogen of mass 3 would recoil in opposite directions except for a small correction due to the momentum of the captured diplon The cloud track method is extremely suitable for an examination of this possibility and I have recently taken expansion chamber photographs of the disintegration particles resulting from the bombardment of a target of heavy ammonium sulphate with diplons, to see if further information can be obtained

Fig 1

The first set of experiments was made with a thin target contained in an evacuated tube at the centre of the chamber Two opposite sides of the end of this tube were closed with mica windows of 6 3 mm and 11 4 cm stopping power respectively The chamber was filled with a suitable mixture of helium and air to increase the lengths of the tracks of the short particles Under these conditions, the particles of 14 3 cm range emerging through the thick window and the particles of 1 6 cm range emerging through the thin window end in the chamber and the usual re projection permits precise determination as to whether the two tracks are co planar and of the ranges Owing to the fine structure of the grid supporting the thin window the efficiency of collection of pairs cannot be high, also the companion to a 14 3 cm particle passing through the thin window would not be able to pass through the opposite thick window In spite of these difficulties opposite pairs of tracks of about 14 3 cm and 1 6 cm range are observed with far greater frequency than could be attributed to chance The photograph reproduced as Fig 1 is a fortunate example the short track on the right being due to the new hydrogen isotope of mass 3 Detailed measurements of the lengths of the tracks and the angles between them are being made and will be published later

To investigate the neutron emission a second series of experiments has been made in which a target of the same material contained in a lead tube of 3 mm wall thickness was bombarded in the same manner, the chamber being filled with a mixture of 50 per cent helium in air Under these conditions, thirty one recoil tracks originating in the gas have been photographed Assuming that these are due to impacts with neutrons the latter appear to constitute an approximately homogeneous group of maximum energy of about 1 8 million volts This energy appears to be in fair agreement with reaction (2) on substitution of the mass of $_2He^3$, which can be estimated from consideration of the energies of the short range products resulting from the transformation of $_3Li^6$ by protons[2,3,4] The $_2He^3$ group of reaction (2) with a possible range of about 5 mm would not pass through the thinnest window used in these experiments but special arrangements are being made to search for them in an expansion chamber

These experiments are the first to be made with a new discharge tube constructed following a design due to Dr Oliphant I should like to acknowledge the much valuable advice which Dr Oliphant has always so readily given me in the course of construction of this tube I am also indebted to him for preparing the diplogen targets used in these experiments

An Artificial Radioelement from Nitrogen

Messrs M Danysz and M Zyw, working in this laboratory, have bombarded diverse substances with α rays from a thin walled glass tube (resulting range about 5 cm) containing some 15 millicuries of radon, and immediately afterwards have tested their activity with a Geiger Müller counter An activity decaying exponentially with a half period of 1 2 min was found on *all* the substances examined, namely, platinum, silver, lead, calcium and nickel No certain influence of the nature of the substance could be ascertained The initial activity was of the order of 50 impulses per minute The effect disappeared when the range of α rays was reduced by two very thin gold foils or a few millimetres of air

In subsequent experiments, a strongly activated platinum wire was used as source In order to avoid contamination, the wire was enclosed in an airtight box, covered with a film of less than 1 mm stopping power The effective range of α rays from radium C′ was 6 5 cm The effect was greatly increased and amounted to about 200 impulses per minute with a source equivalent to 8 mgm radium

An obvious explanation of the effect was that it was due to the recoil of some new radio element produced by the very fast α particles (Incidentally, it has been found that the recoil of radiophosphorus is easily detectable) To test this possibility experiments have been made (*a*) *in vacuo* (*b*) in hydrogen (*c*) in nitrogen (*d*) in oxygen As the effect was apparent *only in nitrogen* we conclude that it consists in a transmutation of nitrogen[1] of the Joliot type, the probable reactions being

$$(1)\ {}_7N^{14} + {}_2\alpha^4 = {}_9F^{17} + \text{neutron} \quad (2)\ {}_9F^{17} = {}_8O^{17} + \text{positron}$$

An examination of the particles entering the counter showed that they are completely absorbed by some 0 5 gm /cm ^{2} of lead An experiment with a magnetic field has shown definitely that the particles are positrons

It appears probable that the transmutation of the Joliot type may be found in all known cases of transmutation of elements involving the emission of protons

Note added to proof We have since found that NaN_3 gives a greatly increased effect which confirms our assumptions

New Source of Positive Electrons

OBSERVATIONS made with a weak radium source placed inside the Wilson chamber in a magnetic field showed that in addition to the β particles of the natural spectrum a very considerable number of positive electrons are also emitted

The radiator consisted of a thin layer of radium salt deposited on the inner surface of a thin walled glass tube This small tube was introduced into a cylindrical protecting tube (of lead in our first experiments and afterwards of carbon) in the wall of which (4 mm thick) a 2 mm opening had been made By this means an almost point like source of β rays was obtained the velocities of which could be measured in the usual way Under favourable conditions tracks of positive electrons could be observed once in every three to four expansions on the average Up to the present 30 tracks have been observed with the following distribution of velocities

Energy intervals (e /kv)	Number of positrons
100–300	8
300–600	16
600–900	6

The number of positrons corresponding to every disintegration can be determined directly by calculating the number of electrons belonging to the natural spectrum, the tracks of which are seen on the same photographs We have calculated the number of β rays with an energy exceeding 1 000 kv , the total number of disintegration electrons was determined according to the well known distribution curve of the continuous spectrum The data obtained clearly show that the number of the emitted positrons are not less than 0 02–0 04 for each disintegrating atom of radium C This unexpectedly high number exceeds by several times the total number of photo electrons in the natural spectrum of radium C (According to Ellis[1] the number of electrons per disintegration of all groups of the linear spectrum of radium C is about 0 009) This comparison makes it highly improbable that the observed positive electrons are due to the internal conversion of γ rays In any event the coefficient of internal conversion which would have to be adopted on the assumption that the observed phenomenon is due to the internal photoeffect from the levels of negative energy exceeds the theoretical value *some hundred times*

The theoretical data available are not sufficient for a comparison to be made A rough estimate can be obtained by assuming the upper limit of the effect which would be still compatible with theoretical considerations to have the following value

Nedelsky and Oppenheimer[2] give for the wave length $\lambda \to 4\ 7$ X U the internal conversion coefficient 5×10^{-4} If we assume that all the γ lines in the spectrum of radium C with $h\nu > 1120$ kv (the number of quanta per disintegration 0 45) undergo internal conversion with the coefficient 5×10^{-4} calculated for the limit of the spectrum, then the number of positive photoelectrons will be equal to $0\ 45 \times 5 \times 10^{-4}$ 2×10^{-4} Thus some new mechanism appears to be involved in the production of positrons being presumably connected with β disintegration

It may be added that Lecoin[3] using the same method of investigation was unable to observe the emission of positive electrons in the case of radium E, where the limit of the spectrum does not very much exceed 2 mc^2 Neither can the observed phenomenon be ascribed to the effect of α particles which has recently been discovered by Curie and Joliot[4] since this would mean one positron corresponding on the average to every 100 α particles

Note added in proof (March 17) More recent experiments have shown that a considerable part of the positrons must be due to the action of the β rays on the walls surrounding the radioactive source A further communication follows

Decay Constant of Radium C

IN previous notes[1] an account has been given of a measurement of the decay constant of radium C The method consisted in determinations of the number of α particles emitted from a beam of recoil atoms from radium C at various distances from the source For the half period a value of the order 10^{-8} sec was found During a continuation of these experiments it was found that the number of α particles emitted from a beam of recoil atoms depended greatly on the temperature of the walls of the apparatus When the walls were cooled by liquid air the source being at room temperature, a large number of α particles were emitted from the wall facing the source From these experiments it was concluded that at room temperature the recoil atoms are at least partly reflected from the walls of the apparatus The dependence of the number of α particles emitted from the recoil atoms on the temperature of the walls indicated that the shape of the decay curve was complicated by the reflection of the recoil atoms from the walls

Since Gamow's theory gives a much greater value for the life period than that found in the experiments with moving recoil atoms, it was thought possible to obtain an estimate of the life period of radium C′ by means of Geiger counters without making use of the recoil phenomenon The arrangement which was finally adopted[2] consisted of two small counters, placed close to one another in a vessel, which was exhausted to a pressure of 5 cm of mercury The central electrodes were connected to the grid of each one of two amplifying valves, each of the anode circuits contained a *moving iron* oscillograph The active material (about 10^{-6} mgm) was placed between the counters By closing the counters by aluminium foils of appropriate thickness, it was arranged so that one of the counters was excited only by β particles, the other by both α and β particles

FIG 1

The deflections of the mirrors of the oscillographs were crossed, so that one mirror gave a horizontal deflection the other a vertical one Light from an arc lamp was reflected successively from the two mirrors and concentrated by a lens on a film, which was moved with a velocity of about 1 cm per second The appearance of the deflections obtained is shown in Fig 1 (*a*, *b*, *c*, *d*) The direction of movement of the light spot on the film is shown by the arrow, *a* shows a true coincidence, in *b* and *c* the counters are excited with a time difference shorter or longer respectively than the duration of the impulse from the counter, for this a value of 1 5 × 10^{-8} sec was obtained in separate experiments, a time difference of a tenth of this could still be detected In *d* the time difference has the opposite sign to that of *b* This type of deflection is not suited for measurements, since the position of the bend is difficult to observe

With radium C as source, a large number of deflections of the types shown in *a* and *b* (or *d*) were observed The sign of the time differences showed that the β particle was emitted before the α particle Deflections of the types *a* and *b* were obtained in about equal numbers, this gives for the half period of radium C a value of 2 × 10^{-4} sec with an accuracy of about 50 per cent A more accurate determination would require a knowledge of the frequency of occurrence of time differences of different lengths Such a procedure would scarcely be legitimate considering that the magnitudes of the impulses from the counters were varied somewhat

The existence of eventual time lags in the action of the counters was tested by using thorium C as source With this substance, only true coincidences were observed, this shows that the time lag in the action of the counters is small compared with 10^{-4} sec

Continuous X-Ray Spectrum from a Thin Target

IN order to investigate the true energy distribution in the continuous X ray spectrum, the target to be used must be sufficiently thin to ensure that the cathode rays passing through it produce only a single excitation For ordinary voltages, metal foils 10^{-4}–10^{-5} cm thick can be used for this purpose The intensity of X rays obtained under these conditions is very low, a fact which prevented Kulenkampff[1] measuring the energy distribution with a crystal spectrometer

It was found possible to investigate the intensity distribution in the continuous spectrum from a thin aluminium foil with an ionisation spectrometer equipped with a Geiger Muller tube counter, instead of the ionisation chamber The aluminium foils used had an initial mean thickness of 5 5 × 10^{-5} cm, under the bombardment by cathode rays the thickness decreased to such an extent that the cathode spot became semi transparent, corresponding approximately to the thickness of 1 × 10^{-5} cm, all the measurements were performed with these thinned foils

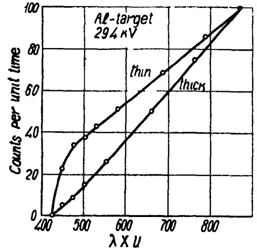

FIG 1

The ionisation spectrometer was set at an angle of 90° between the X rays and the cathode stream The rays were analysed by a calcite crystal, and entering the tube counter along its axis, did not strike the walls or the central wire The counter was filled with a mixture of argon at a pressure of 46 cm and air at 10 cm

Intensity distribution measurements in the wave length region from λ_0 to $2\lambda_0$ (λ_0 is the high frequency limit of the spectrum) from thin targets were made at voltages of 20, 30 and 40 kilovolts For comparison, analogous measurements were repeated with a thick aluminium plate The intensity curves directly obtained in both cases at 30 kv are shown in Fig 1 Similar results were obtained at the other voltages

The following points must be considered in order to deduce from these curves the true energy distribution (1) absorption of the rays on their path from the target to the counter, (2) incomplete absorption in the counter, (3) finite slit widths, (4) wave length dependence of the reflection coefficient of the crystal In the case of the thick target, the absorption in the target itself must be also taken into consideration

Applying the corresponding corrections and calculating from the number of quanta recorded by the counter the energy one can finally obtain the true energy distribution in the spectrum

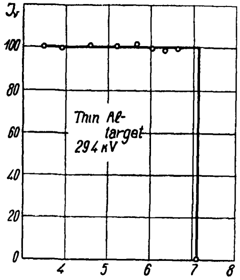

FIG 2

For thin targets the energy is found to be independent of the frequency from ν_0 to $\frac{1}{2}\nu_0$ At the high frequency limit ν_0 there is a sharp discontinuity (Fig 2) This result is in accord with Sommerfeld's[2] theory of the continuous spectrum For the thick target the well known energy distribution as represented by Kulenkampff's formula is obtained

Vibrational States of Rb_2 and Cs_2

THE channelled bands of rubidium and cæsium have already been studied by many authors but the analyses of the vibrational states have not been completed By close examination of the spectrograms which I have obtained with a plane grating and a quartz lens of three metres in focal length I have found the vibrational structures of the bands and made an attempt to analyse them In the case of rubidium the frequencies of the heads of the bands may be represented as follows

For the red system

$$\nu = 14666 + 47\ 3(n + \tfrac{1}{2}) - 0\ 15(n + \tfrac{1}{2})^2 - 57\ 8(n'' + \tfrac{1}{2}) + 0\ 14(n'' + \tfrac{1}{2})^2$$

for the blue system,

$$\nu = 20930 + 38(n + \tfrac{1}{2}) - 0\ 3(n + \tfrac{1}{2})^2 - 57(n'' + \tfrac{1}{2}) + 0\ 1(n'' + \tfrac{1}{2})^2,$$

for the violet system,

$$\nu = 22968 + 38(n + \tfrac{1}{2}) - 0\ 0(n + \tfrac{1}{2})^2 - 59(n'' + \tfrac{1}{2}) + 0\ 1(n'' + \tfrac{1}{2})^2$$

In addition to these three systems another one at 8800 A was also observed with a spectrograph with a lower dispersion

It is generally accepted that the ground state of the molecules of other alkali metals is Σ_g^+ and there are two excited states Σ_u^+ and Π_u above this The system observed in the near infra red at 8800 A may be due to the transition $\Sigma_u^+ \leftarrow \Sigma_g^+$ and it is considered that the red one is due to the transition $\Pi_u \leftarrow \Sigma_g^+$ while the blue system may correspond to the blue band system in potassium

In the case of cæsium I have tried to arrange 83 heads of the red system at 6300 A which has already been measured by Rompe[1] but not analysed The formula is as follows

$$\nu \quad 15801 + 25\ 7n \quad 40\ 0n''$$

As a result of the lack of heads corresponding to the higher quantum numbers and the slowness of convergency the terms of the second order were omitted In the band system at 7600 A 38 heads were measured and were arranged as follows

$$\nu \quad 13040 + 33\ 7n \quad 41\ 3n''$$

The other band system at 7200 A was also photographed but the close crowding of the heads near the system origin makes it very difficult to measure the heads From the measurements of 16 heads in the region of longer wave lengths it was known that the vibrational quanta of the lower and the upper states were 39 cm^{-1} and 29 cm^{-1} respectively A new absorption band was observed in the infra red spreading from 8735 A to the farther infra red

In the case of cæsium four band systems were observed near the resonance doublet but there are only two systems in other alkali metals Probably at the upper level of the system at 8700 A and 7600 A the molecules will dissociate into a normal and an excited $^2P_{1/2}$ atom while at 8200 A and 7200 A they dissociate into a normal and a $^2P_{3/2}$ atom

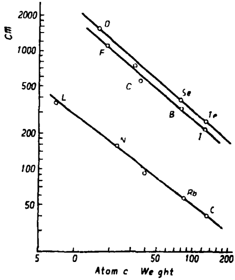

FIG 1

The strong absorptions at the shorter wave length end of the band observed in the cæsium, are due to the fact that on one branch of the Condon parabola the wave lengths of the heads are nearly constant

It is very interesting to remark here that the logarithms of the vibrational frequencies in the ground states of the molecules of five alkalis and of four halogens, together with four elements in the sixth group in the periodic table, vary linearly with the logarithms of their atomic weights, as shown in the accompanying figure (Fig 1) The points corresponding to K, Cl S were displaced downwards This anomaly appears also in the fifth group N, As, Bi lie on a straight line and P below the line

Full accounts of the experimental results will shortly be published elsewhere

Stark Effect for the Hydrogen Isotopes

RECENTLY we have taken several photographs of the Stark effect in a mixture of the two hydrogen isotopes, using deuterium kindly supplied by Prof Urey The measured zero field separation of each pair of Balmer lines persists in high fields with small variations as noted below

The minimum field for good resolutions in the Stark effect is fortunately the same for nearly all the Stark components of each Balmer pair It varies, however, from about 50 kv /cm in $H_\delta^{1,2}$ to 130 kv /cm in $H_\alpha^{1,2}$

From left to right in the accompanying photograph (Fig 1) of $H_\gamma^{1,2}$ one finds alternately components of H_γ^2 and H_γ^1 The maximum field of 52 kv /cm is sufficient to show the character of the lines, and to separate completely the two Stark effects

The displacements are not exactly those given by the Epstein theory even when one allows for the second order effect The irregularities are made especially clear in the present analysis through variations in the separation of protium-deuterium pairs of Stark components At maximum field, the pair of moderate intensity immediately to the right of the centre of the σ image (Epstein $\Delta = 3$) have a separation 9 per cent higher than that of the corresponding pair on the left The contrast is even more pronounced in the π images From the evidence it appears improbable that these irregularities are constant for all field strengths According to measurements on $H_\gamma^{1,2}$, they are too large to attribute entirely to variations in the fine structure separations for the two isotopes

In moderately high fields, the central σ component of H_γ^2 appears to swing sharply to the red as though the second order effect were abnormally high This is found to be due to a superposed new molecular line which is clearly resolved through its large red shift in fields of 70 kv /cm Like most molecular lines on our plates, the new line has appreciable intensity only in rather high fields With a given mixture of isotopes, we find that at zero field the deuterium line is always stronger in $H_\gamma^{1,2}$ than in $H_\beta^{1,2}$ In the accompanying photograph, the light hydrogen line is clearly much the stronger in the normal spectrum With the application of even low fields, however, the energy passes more to H_γ^2, so that at maximum field the two patterns are of almost equal strength The intensity variations suggest as their principal origin collisions of the second kind between atoms of the two isotopes This phenomenon might be expected to become most prominent in cases of perfect resonance which exist at fields where components of the isotopes cross In the region between the strong central σ components, and at moderate fields it may be noticed that a component of H_γ^2 persists while the component of H_γ^1, which should cross at this point, is certainly weaker and appears to be lost On the above grounds, one may tentatively say that collisions of the second kind are more probable when the light atom is the one excited There may be however, a selective action whereby certain pairs of isotopic states are preferred in energy transfers , for the relative intensities of corresponding components of H_γ^2 and H_γ^1 are clearly not constant throughout the photograph, and in $H_\beta^{1,2}$ these fluctuations are more marked This amounts to the statement that there are departures from the Schrödinger intensities, and that the departures are not the same for the two isotopes

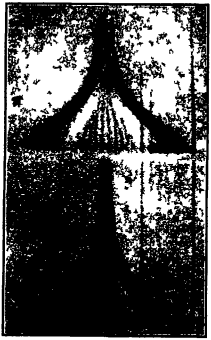

FIG 1 The spectral line $H_\gamma^{1,2}$ in fields up to 52 kv /cm

A great many new molecular lines are found with moderate displacements The research is being extended to include a study of the molecular spectra as well as the atomic spectra with varying proportions of the isotopes

Explosions occur in Lo Surdo sources when a small amount of oxygen is allowed to mix with the deuterium at a total pressure of one to two millimetres Under such conditions, explosions are not observed with light hydrogen In the present case they appear to be set off by a rather intense heating of the cathode surface

Absorption Spectra of Chlorophylls *a* and *b* at Room and Liquid Nitrogen Temperatures

THE absorption spectra of ether solutions of chlorophylls *a* and *b* prepared by the method described earlier[1] were photographed at the temperature of liquid nitrogen A Steinheil spectrograph and panchromatic plates were used for the spectral region λ 4100–6700 A Pyrex glass absorption cells with internal thickness of 1 mm contained the solutions Four plane quartz windows in the walls of the Dewar vessel permitted parallel light to pass from the Mazda source through the liquid nitrogen bath and the solid solution of chlorophyll in ether to the spectrograph slit The slit width was 0 02 mm The photographs were taken as soon as possible after freezing the solutions because the development of cracks in the solid ether solution caused it to become rather opaque in two hours

In the following table is a comparison of the absorption maxima measured at room temperature by a spectro photoelectric method[2] and those measured at 196 C by the photographic method The bands at room temperature are listed in order of their decreasing absolute intensities The band intensities at 196 C are listed in decreasing order as they appear on the plates

Wave-lengths of Absorption Maxima at

	25° C	− 196° C
Chlorophyll *a*	4275 A	End absorption to 4520 A
	6600	6640
	4100	4920
	6125	6320
	5725	6180
	5275	6015
	49 5	5760
		5365
Chlorophyll *b*	4525	4770
	4300	6510
	6425	4420
	5925	6000
	5675	6350
	5475	5760
	5025	5480

At − 196° C the absorption bands are considerably narrower than at room temperature and their maxima are shifted Absorption spectra of fraction *c* [1] at − 196° C were intermediate between those of components *a* and *b*

Investigation of Paraphysical Phenomena

A CERTAIN interest in the physical aspects of psychical research has recently been shown in these columns[1] In view of the fact that the controversy seems to turn mainly upon the alleged paranormal or extra-contemporary physical powers of Rudi Schneider, it may be worth while briefly to record a series of experiments with that medium, although the results are merely of a negative character Full experimental details will in due course be published in the *Proceedings of the Society for Psychical Research*

Sittings were held about twice a week from October 1933 until March 1934 inclusive in the *séance* room of that Society No evidence of absorptions of a beam of infra red light of the type recorded by Osty[2] and Herbert[3] could be obtained notwithstanding frequent announcements by the trance personality that the force had entered the ray The apparatus used was (1) a Moll galvanometer with Moll thermopiles and (2) a Westinghouse copper–copper oxide photoelectric cell in series with an Einthoven galvanometer In both cases the sensitivity and the precautions taken against electrical leaks, vibration and stray heating effects were such that an absorption of one half per cent could be detected All visible light was excluded from the beam by a sheet of ebonite of thickness of 0 005 cm or by a filter of 1 cm of a saturated solution of iodine in carbon disulphide in a glass vessel or by both For this solution Coblenz gives the following transmissions

Transmission	Per cent	Transmission	Per cent
0 75μ	0	3μ	60
1 0μ	80	4μ	10
1 2 5μ	90	5μ	0

This filter was used because the photographic work of Rayleigh[4] and Herbert indicated that absorptions did not occur at wave lengths shorter than 1μ while Herbert and Osty using photocells which cannot have been sensitive beyond 5–6μ both recorded absorptions The thermopiles should have been both sensitive and rapid enough to detect absorptions of the type previously recorded and the surface density of illumination was kept low as this is supposed[3] to increase the chance of observing absorptions The possibility of short period absorptions was negatived by the use of the photocell

A cinema camera was installed with a film sensitive to the infra red supplied by Messrs Ilford and it was found possible to obtain sharply defined moving pictures in a feeble red light By increasing the flood lighting and using horn or ebonite filters it is confidently expected that cinema films could be taken in total absence of visible light By this means, motion pictures of telekinetic phenomena could be obtained in a light that is innocuous to the medium No evidence however could be obtained of the telekinetic phenomena recorded by Price[5] and others, with the exception of a considerable number of movements not exceeding 10 cm of a hanging curtain In order to determine whether these were due to draughts a strip of tinfoil about a foot in length was so hung about 5 mm from a vertical metal plate that a slight draught brought them into contact and rang an electric bell The whole was so placed that the force had ready access to it and that draughts could not affect it Under these conditions the bell did not ring though the curtain continued to move

The force on several occasions was announced by the medium in trance to have gone into one of a pair of cotton wool lagged boxes and remained there for a period of some 15 minutes If any change in the difference of temperature between the two boxes was produced during this period a copper–constantan thermocouple showed that it was less than 0 003° C

During a period of half an hour the force could produce no significant difference in the rate of growth of two strains of *Bacillus fluorescens* or in the fermenting power of yeast

A comparative investigation of the medium s personalities normally and in trance was undertaken by means of the word association test in conjunction with the observation of the psychogalvanic reflex A preliminary scrutiny of the results shows that Olga', the trance personality has a vocabulary limited to the few words used by her during the ordinary sittings

It has been alleged that the trance personality is aware of what goes on in the dark *séance* room[5,6] in these sittings this was not found to be the case

The rate of breathing of the medium in trance ranged in these sittings from 90 to 260 cycles per minute continuing with two or three intervals of some 15 minutes each for 5 to 6½ hours The longest continuous period was 2½ hours with frequent stops totalling about 10 minutes In view of the fact that this respiration has been regarded as a remarkable physiological phenomenon samples were collected and analysed by Dr C G Douglas showing that the medium in no way overbreathes As the rate of respiration increases so its depth decreases the total oxygen consumption per minute observed never exceeded 1410 c c at N T P which corresponds to a man walking some four miles an hour During trance this medium is in constant often violent movement so that these results are in no way paranormal Moreover we have found no difficulty in imitating his breathing

Every suggestion made by the medium and the trance personality was acted upon and both repeatedly expressed their satisfaction with the arrangements and with the investigators On our side it is impossible to speak too highly of Rudi Schneider s willingness to submit to every suggested test and control, he acted throughout with the most scrupulous straightforwardness

Transformation of Yellow Mercuric Iodide into the Red Form

RODWELL and Elder[1] have observed microscopically that when yellow orthorhombic crystals of mercuric iodide are touched the change into the red variety continues through the whole mass of crystals and the resulting pseudomorph consists of minute octahedrons of the red form

It is well known that the yellow form crystallises from a solution of mercuric iodide in alcohol and exists for varying lengths of time On viewing under the microscope single crystals free from etched markings the change from the yellow into the red variety is found to be in accordance with the usual type observed in solid reactions After about 15 minutes nucleation usually occurs along the whole length of the crystal edge the interface then advances rapidly across the crystal parallel to the opposite edge Occasionally nucleation occurs as a thin strip in the interior of the crystal parallel to the edges the interface then moves out towards the edges of the crystal with approximately the same linear rate in both directions It appears that nucleation occurs along some weak axis in the crystal and immediately spreads along the whole length, the reaction proceeds with the usual parallel advance At 20° C the mean linear rate of advance of the interface was 0 0025 cm /sec

By heating the red variety very much smaller rhombohedra of the yellow form were volatilised on to a cover glass Such crystals commenced to change into the red form after about five hours the reaction spreading inwards very slowly from all four edges with the usual parallel advance of the interface octahedra of the red form could be observed in the decomposed part of the crystal

The linear advance of the interface parallel to the edges of the crystal has previously been observed in the case of true decomposition for example potassium hydrogen oxalate hemihydrate[2] and potassium chlorate[3] and it appears to be characteristic also of the transition from one crystalline form into another of polymorphic substances

Investigation of the reaction is proceeding

Rate of Nucleation of Copper Sulphate in Vacuum

THE rate of growth of the centres of dehydration of $CuSO_4 5H_2O$ varies with the crystal direction On the large faces of the crystal the nuclei grow in the form of a cross and the direction of the arms of the cross are parallel to two of the crystal axes The underlying surfaces of the nuclei prove to be very complex for a disc of dehydrated material is found to be suspended from the longer arm of the cross This disc passes into the crystal at an angle of approximately 33

Counts have been made of the rate of production of centres of decomposition on the surfaces of a crystal when this has been removed from the saturated solution carefully dried and placed in a high vacuum No visible nuclei appear at room temperature until after an induction period which is of the order of 100 minutes at 18° C Thereafter the number of nuclei increases at a linear rate The length of the induction period decreases with increasing temperature but on account of variations in the behaviour of individual crystals it has not been possible to determine the temperature coefficient Scratched crystals give shorter induction periods and crystals with irregular surfaces give larger numbers of centres than more perfect crystals

The induction period is most probably due to the slow rate of growth of the nuclei when first formed this rate being much slower than that of visible nuclei It is thus incorrect to assume in all cases of solid decomposition that the outward rate of growth of the nuclei is constant at all stages in their growth[1] In the decomposition of barium azide where the rate of decomposition is given by $dp/dt \sim t^{10}$ and in that of mercury fulminate where $dp/dt \sim t^{24}$, the observed induction periods are in the main to be ascribed to an accelerating rate of nuclear growth

Photochemistry and Absorption Spectrum of Acetone

IT has been generally assumed that the explanation of the diffuse absorption spectra of aldehydes and ketones in the ultra-violet is the occurrence of a process of predissociation involving the splitting of a C – H or C – C link[1]. Against this observation are the following observations:

(1) The vapours of aldehydes and ketones exhibit fluorescence.

(2) The unimolecular decomposition is always accompanied by bimolecular polymerisation.

(3) The quantum efficiency of decomposition is diminished on passing from C – H to C – C compounds.

(4) Complex ketones decompose in quite a different way from acetone, giving very little carbon monoxide.

(5) The photodecomposition is not a chain reaction.

The photo-reactions of acetone illustrate (1) and (2). In the gaseous state it decomposes with a quantum efficiency of about 0·2 only[2], and we have found that in the liquid state it polymerises (without decomposition) with about the same quantum efficiency. As it is difficult to assume a back reaction to explain the low efficiency[3], it seems more probable that no splitting of a link occurs in the excited molecule. Instead, two processes may occur: (i) bimolecular interaction to give polymerisation; (ii) unimolecular decomposition through the similar interaction of two parts of the molecule, for example:

$$\begin{matrix}CH_3\\CH_3\end{matrix}\!>\!CO \longrightarrow \begin{matrix}CH_3\\|\\CH_3\end{matrix} + CO$$

In the case of the ketone $\begin{matrix}CH_3CH_2CH_2CH_2\\CH_3\end{matrix}\!>\!CO$ the products are not unexpectedly $\begin{matrix}CH_3 & CH\\ & \|\\ & CH_2\end{matrix}$ and $\begin{matrix}CH_3\\CH_3\end{matrix}\!>\!CO$[4].

Unless the above unimolecular dissociation takes place within a rotational period, it becomes necessary to find another explanation of the diffuseness of the absorption spectrum of some of these substances. We have recently examined the absorption spectrum of acetone, using pressures 0·5–200 mm in absorbing columns up to one metre. With pressures higher than a few mm a region of continuous absorption extends from c. 3200 A. to 2400 A., with a maximum at about 2800 A. This is the region characteristic of compounds containing the > C = O group. At lower pressures in longer columns and under higher dispersion (Hilger E_1 spectrograph) this continuum splits up into about four groups each containing about 25 diffuse bands. The centres of the respective groups lie at c. 3150, 2900, 2710 and 2570 A. The corresponding intervals are 2740, 2420 and 2010 cm^{-1}. (A strong Raman frequency of acetone is 2900 cm^{-1}.) The width of the bands is of the order 2·5 A. (c. 30 cm^{-1}) and their separation uniformly about 4 A. With increasing pressure the bands widen and the groups extend so as to produce an effectively continuous absorption.

This type of equally spaced diffuse narrow diffuse bands is similar to that found in other *Y*-shaped molecules[5]. Assuming that the CH_3 groups of acetone behave as single masses of 15, and using probable interatomic distances, the moments of inertia of the *Y*-shaped molecule are such that the rotation lines in the bands should be separated by only *c.* 0·4 cm^{-1}. There will, moreover, be a double series of *P* and *R* branches. It seems therefore inherently impossible to detect the fine structure in this spectrum, and the diffuseness of the bands can be attributed to an unresolved close packing of the rotation lines without calling upon the additional hypothesis of predissociation.

In the case of formaldehyde, where the moments of inertia are much smaller, it is not surprising that a region of fine structure is observed followed by diffuse bands, indicating unimolecular rearrangements within periods greater or less than those of rotation.

Activated Adsorption and Para-Ortho Hydrogen Conversion on Charcoal

THE para-ortho hydrogen conversion was used by us, among other reactions, at the suggestion of Prof. A. Frumkin, in order to investigate the chemical properties of hydrogen adsorbed on charcoal at high temperatures.

It has been shown in a qualitative way by Harkness and Emmett[1] and by Rummel[2] that adsorption of hydrogen on the surface of catalysts diminishes their activity in the ortho-para hydrogen conversion at 90° K.

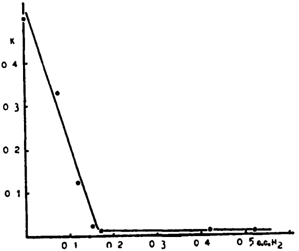

FIG. 1. Adsorption of hydrogen on charcoal at 500° C.

We have investigated the relation between the velocity of the para-ortho conversion at 20° C. and the quantity of gas adsorbed in the activated form. The charcoal was outgassed at 950°, then allowed to cool to the temperature of hydrogen adsorption, and after a definite amount of gas was adsorbed, further cooled to room temperature. The velocity of the para-ortho conversion was measured at 20° C using the dynamic method These experiments (Fig 1) have shown that the half period of the reaction τ falls in an almost linear way when the quantity of hydrogen adsorbed at 500° increases The adsorption of 0 17 c c hydrogen on 1 gm of charcoal brings down the velocity to almost zero, this quantity of hydrogen covers less than one thousandth part of the surface Further increase of the quantity of adsorbed hydrogen has practically no influence on the velocity of the reaction The poisoning action of hydrogen adsorbed at high temperatures is also observed when the para ortho conversion was carried out at 300° but the measurements in this case are inaccurate because hydrogen is already adsorbed with a measurable velocity in the activated form at 300° and the catalyst is therefore gradually poisoned during the reaction

The change in catalytic activity caused by the activated adsorption cannot be explained merely by a diminution of the van der Waals adsorption[3] as experiments which we have carried out have shown that the latter is practically uninfluenced by a previous activated adsorption of 0 17 c c of hydrogen

A Reducing Substance in Brain Tissue

EXPERIMENTS in this laboratory on the chemical basis of some histological staining reactions of brain tissue have shown that all the brain tissues examined (mouse rat, guinea pig, ox) contain a substance which has the peculiar property of reducing silver nitrate in neutral or acetic acid solution at room temperature, although ammoniacal silver nitrate is not readily reduced in the cold Extracts of brain tissue containing this substance reduce phenol 2 6 dichloro indophenol under the conditions described by Harris and Ray[1] and Birch, Harris and Ray[2] for the estimation of ascorbic acid in tissues and aqueous alcoholic extracts of ox brain tissue contain the reducing equivalent of 12–15 mgm of ascorbic acid per equivalent of 100 gm of tissue, as determined by this method But the general properties of this substance (or substances) clearly differentiate it from ascorbic acid, as shown in the following table

Brain reducing substance	Ascorbic acid
Readily reduces acid ammonium molybdate at room temperature	Does not readily reduce acid ammonium molybdate at room temperature
Does not reduce ammoniacal silver nitrate at room temperature	Instantaneously reduces ammoniacal silver nitrate at room temperature
Insoluble in absolute acetone	Soluble in acetone
Precipitated by mercuric acetate	Not precipitated by mercuric acetate
No anti scorbutic activity	Anti-scorbutic activity

Daily doses of ox brain extract containing the reducing equivalent of 6 mgm of ascorbic acid failed to prevent the appearance of the symptoms of scurvy in guinea pigs fed on a scorbutic diet, and it is clear that estimations of ascorbic acid in brain tissue by the indophenol titration method yield fallacious results

The activity of solutions of this reducing substance is easily destroyed in both acid and alkaline solutions, which renders concentration difficult, but experiments are proceeding with the view of its isolation, solutions are somewhat stabilised by the addition of cyanide, which suggests the possibility that sulphur is concerned in the activity of this substance A crystalline semicarbazone, m p 251°–252° C (uncorrected), has been isolated from active extracts, but it is not yet possible to determine whether or not this is a derivative of the active substance

The possibility of identity of the reducing substance from brain tissue and that obtained from tumour tissue by Boyland[3] and Harris[4] is under consideration but it is not proposed to name the substance from brain tissue yet

Serum Phosphatase in the Domestic Fowl

IT has been suggested that skeletal reserves of calcium may be available for eggshell formation in the domestic fowl[1] If this suggestion is correct, alterations in the metabolic activity of the bony tissues might be expected in association with the laying period in the hen Moreover, plasma phosphatase has been used to study alterations in calcium and phosphorus metabolism in sheep[2] and the association of increased serum phosphatase with clinical disorders of bone is now fairly well established As opportunity has arisen therefore serum phosphatase estimations have been made on birds at different stages of the reproductive cycle using Bodansky's technique[3] and his definition of the unit of phosphatase Some of the results secured so far are given

Birds used	Units of Serum Phosphatase
3 Cockerels	4 1 4 0 3 0
15 Laying Pullets	9 2 7 5, 27 1 10 2, 28 3 8 3 8 3 16 4 13·0 9 2 15 4 6 9, 27 7 16 7 22 6
2 Pullets in moult after laying	24 0 13 9
9 Pullets, sexually immature	4 4 3 2 2 0 4 3 1 7 3 8 3 6; 5 3 2 8
1 Pullet nearing laying (weight of largest ovum in ovary = 4 4 gm)	12 1

The values for cockerels and sexually immature pullets are comparable those for laying and moulting birds are higher There may well be a physiological increase of serum phosphatase in the laying hen, although it is realised that the increase may be related to functions other than bone metabolism and shell formation

The values obtained from laying birds are very variable, and it will be desirable to study these variations in relation to egg production

Negative Oxidation-Reduction System of *B. coli*

STEPHENSON and Stickland (1931)[1] demonstrated in *B coli* an enzyme which could catalyse the reduction of methylene blue by molecular hydrogen Examination of this reduction process discloses a striking resemblance to the hydrogen electrode

$$(1) \quad H_2 \xrightarrow{\text{bacteria}} 2H^+ + 2e$$

$$(2) \quad H_2 \xrightarrow{\text{platinised Pt}} 2H^+ + 2e$$

In other words, the bacterium behaves like a platinised platinum surface in bringing molecular hydrogen into equilibrium with hydrogen ions We have investigated the reversibility of this reaction of *B coli* using as an indicator γ γ dimethyl dipyridyl, the E_0 of which lies in the range of the hydrogen electrode from *p*H 7 9

The reversibility was tested (1) by maintaining the *p*H at a constant level and varying the partial pressure of hydrogen, and (2) maintaining the partial pressure constant and varying the *p*H The observed potentials agreed well with the theoretical potentials calculated for the hydrogen electrode under identical conditions This reversible hydrogenase system of *B coli* is the most negative oxidation reduction system as yet described in living cells The complete experimental details will be published shortly

Origin of African House Rats

THREE main types, or mutations, are known of the common house rat (1) a grey type with grey belly (*Rattus rattus rattus*, Linnæus) (2) a brown type with grey belly (*R r alexandrinus* E Geoffroy) (3) a brown type with a creamy belly (*R r frugivorus*, Rafinesque)

From an analysis of the distribution of the wild stock it has been possible to show that this wild stock represented by *R r frugivorus* originally came from north west India the wild race inhabiting the lower Indus Valley being identical with it, this race is the westernmost of the wild local races of *R rattus* and is connected by intermediate types with the other races found in India and Malaya Rats of the stock developed from this type are common all over Africa, the white bellied type being imported by coast shipping, and the grey bellied overland up the Nile Valley so far as Uganda, in the trail of overland traffic, or even earlier with the immigration of the cattle raising tribes from the north It has recently been possible to show that in addition to the *frugivorus* stock, and its mutations, another race of Indian rat has been material in building up the house rat population of East Africa Both the wild cream bellied (*R r wroughtoni*, Hinton) and a parasitic grey-bellied mutation (*R r rufescens*, Gray) of the more rufous South Indian rat have been found on Zanzibar Island, in central Kenya, and as far inland as Uganda They probably came from India by shipping on the Bombay-Goa Zanzibar track

The possibility of analysing an introduced rat population appears to be of importance as it is much easier to trace the origin of these rats than that of either man or fleas carrying disease It will probably be found that the history of the Uganda plague centre can be reconstructed in this way It looks as if the various types keep separate, and that they differ in their biology It is not known at present whether the different races and mutations of house rats differ in their susceptibility to or immunity from plague, although certain observations would point in that direction

An Ancient Foxtail Pine

MY young friend Mr Allan Caplan has recently obtained a remarkable series of fossil plants in the Miocene shales at Creede, Colorado Among these the conifers are especially interesting, and one specimen consists of a small cone, about 19 mm long broadly oval in form, the scales armed with long prickles (Fig 1) I sought the advice of my colleague, Dr Edna L Johnson, who at once produced some immature cones of *Pinus aristata* Engelmann, the foxtail pine of the western mountains of the United States On comparison it was impossible to see any difference Knowlton (1923) described a *Pinus crossii* from Creede, based on foliage which does not appear to differ from that of *P aristata*

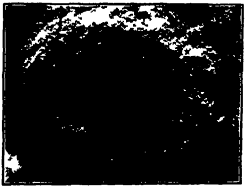

FIG 1 Cone of *Pinus aristata crossii* (enlarged) Photograph Hugo Rodeck

In common with other writers I have assumed Miocene species to be distinct from their modern relatives, even when the visible differences were slight, and such as might indicate only a variety or form in the modern flora Considering the millions of years intervening, it has seemed reasonable to assume that the species would be different and to suppose that if we had the complete plants, other differences than those recorded would be apparent What shall we do, however when there are no visible differences ?

In a paper recently received[1] on the Miocene flora of Oregon, Mr H D MacGinitie proposes a new species, *Acer negundoides*, based on fruits which he says are plainly referable to *Acer negundo*, L ' He not only fails to cite any differential characters for his species, but also expressly states that there are none, so far as the material shows Similarly, the foxtail pine from Creede appears to have no characters separating it from the living tree In such cases it appears premature to offer a new specific name, though an argument can be made, that in all probability the plants are not identical, and only appear so owing to the lack of adequate fossil materials Perhaps the most reasonable compromise would be to use trinomials, in the cases referred to, *Pinus aristata crossii* and *Acer negundo negundoides* This system at any rate enables us to avoid committing ourselves to the doctrine that the plants are positively, and in all respects, identical

From a general biological point of view, it is relatively immaterial whether the Creede fossil pine is exactly the same as the modern one The significant thing is, that it is substantially the same, and that this type of pine has existed in these western mountains of the United States from the Miocene down to the present day In all this time, like the snail genus *Oreohelix*, it seems to have occupied the same general area the higher elevations of our south west country It has not spread into Mexico British America or the eastern United States It is an isolated type, but a Californian species, *P balfouriana*, may be regarded as an offshoot from it

It seems probable that the Creede flora may be essentially contemporaneous with that of Florissant though very different in most of its species Creede is to day at a considerably higher elevation than Florissant, and presumably was so in Miocene times If two floras of the same age, but from different elevations, are preserved in a now temperate region the one from the higher elevation may be expected to resemble most that now living in the same district and hence may be regarded as more modern Very few high altitude Tertiary floras have been preserved, so that at Creede assumes more than ordinary importance

Heredity of Aniridia

A very remarkable pedigree of aniridia was published in 1915 by an American ophthalmologist Samuel Risley It was undoubtedly issued in good faith by a man, now dead, who accepted, without verification the statement of a hospital patient who suffered from the defect This almost blind man aged 27, described the occurrence of a total absence of iris in 111 of his 119 relations in four generations, he gave, moreover, the age, or age at death, and the Christian name of most of these 119 relations, his statement was confirmed, from hospital notes, in the case of one individual only

Now this pedigree is such as to arouse instant mistrust on the part of a geneticist A few years ago I took some considerable pains to get in touch with the family to obtain support for the facts These efforts met with no success, and I was ultimately advised by the late Dr Lucien Howe, a former president of the American Ophthalmological Society, who had also inquired into the matter, that the history was entirely untrustworthy and should be suppressed

Risley could never have considered the facts presented to him by his junior house surgeon', for he even includes the statement concerning one case of *bilateral* aniridia, that the woman had one blue eye and one black eye

Unfortunately, the history has been repeatedly reproduced in America and in Great Britain, recently it has been made use of for propaganda purposes[1] It was even presented to the Prevention of Blindness Committee by a witness who was called, as an expert to advise on the prevention of blindness due to hereditary causes

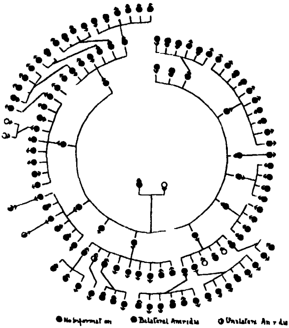

Fig 1

A warning regarding the pedigree in the Nettleship Memorial Volume' has been, apparently ineffective I therefore append a copy of the pedigree (Fig 1) and hope my warning will be supported by the publication of this letter in Nature

Thermal History of the Earth

Prof Arthur Holmes has written to me to point out that I have misunderstood his meaning in his recent paper on the above subject[1] In this paper he states (p 187 and Fig 9, p 179) that the condition for permanent convection currents to be possible in the earth's crust below a certain depth is that the adiabatic and freezing point gradients of the fluid substratum should become tangential at that depth I assumed that he meant that, if the actual numerical values of the two gradients at various depths were plotted against the depth, the two resulting curves would touch at the critical depth, and that consequently if the freezing point gradient were greater above this depth it would also be greater again below it

What Prof Holmes actually intended was, that if starting at any point on the freezing point against depth curve, we plot a second curve giving the temperatures of a column of liquid in convective equilibrium, there would be a certain depth at which these two curves become tangential. This means that below this depth the freezing point gradient is less than the adiabatic gradient, which is, as is well known, the correct condition for the existence of permanent convection currents in a liquid radioactive column cooled slowly at the top and in contact at its highest point with its own solid.

On re-reading Prof. Holmes's paper and carefully examining his curves, I see that the latter view is what he expressed, and I should like to take this opportunity of apologising to him for misrepresenting his real opinion in my recent paper on 'Some Difficulties in Current Views of the Thermal History of the Earth'[2]. There is, I think, little doubt that the requisite condition will be satisfied at some depth in the crust. The available data are insufficient to fix the depth, but such as they are, point to a value of some hundreds of kilometres[3].

Surface Markings of the Henbury Meteorites

DR. L. J. SPENCER, in describing the Henbury meteorites[1], states: "The surface markings . . . in all cases appear to be the result of sculpturing by weathering processes. No clear evidence was detected that the original surface on any of the masses had been preserved." Having examined nearly all the irons found at Henbury, both by our parties from the Kyancutta Museum and by prospectors and others, I consider that Dr. Spencer's statement needs qualification.

The irons buried to considerable depths are certainly rusted and have lost all resemblance to the original surface markings, and the same is true to a less extent of the buried portions of those irons which were only partly exposed, whilst other rusted irons have been at one time buried, but exposed later by lowering of the ground surface. Omitting further reference to these rusted irons, there remain two groups of material which I regard as exhibiting clearly the original surface markings.

The clearest evidence of unweathered condition is found in many of the twisted slugs torn from crater meteorites in landing or in the subsequent explosion. These have cuts, scratches and bruises which cannot be attributed to wind erosion or other forms of weathering, but are as clear and fresh as if recently made. This evidence, if accepted, indicates a probability that some of the individual irons may be in equally fresh condition, and several such have been actually found. (See Plate XV, Fig. 10, 1 c.) These 'individual' irons show a variety of surface markings. Apart from the rust pitted, partly buried surfaces, and the 'pock marks' which are admittedly the result of atmospheric weathering, these markings may be classified as (1) blebs, bosses and rounded ridges, somewhat resembling brain convolutions, (2) 'gouge marks', well shown in the plate mentioned, (3) wide, very shallow concavities. I am inclined to relate these three types respectively to the forward, lateral and hinder parts of the meteorite in flight; but all three types are not necessarily present on a particular specimen, the variation being perhaps due to the amount of rotation and the general shape.

An interesting point is that the size of these markings corresponds roughly with the size of the iron. Thus the gouge marks in the iron of 33 lb. shown in the plate mentioned average ½ in. across, those on a very perfect little 4 oz. iron are only ⅛ in., and those on the largest iron I have seen average an inch. This grading of size would be difficult to explain on the assumption of atmospheric weathering, but on that of flight pitting it may be accounted for by the fact that small irons would lose their velocity and incandescence in the upper rarified air, whilst large ones would retain these in the lower denser levels.

The totally different surface markings of an individual meteorite and a slug cannot be accounted for by weathering. Irons of both kinds, lying on the surface, have been exposed to identical conditions, and had a substantial thickness of iron been removed by weathering, the surface sculpturing of both varieties should tend to approximate, as is admittedly the case with buried and rusted irons.

Not only do the best of the individual irons show these clearly defined forms on their exposed surfaces, but in many instances, especially in recesses of pits, there remain traces of a peculiar even scale, which I regard as the original scale formed in flight. This, in common with the remainder of the exposed surface, is covered by a limonite glaze of secondary origin, due to hydration of a thin film of the original surface scale and iron; this glaze forms an extremely hard protective patina and may be responsible for the perfect preservation of the surface features.

The flight pitting of an iron meteorite differs from that of a stone one. Stone is only subjected to incandescence and gaseous flow (compare the welding torch of an oxy-acetylene blowpipe), whereas iron is subjected to oxidation as well (compare the 'cutting torch' in which an additional nozzle sprays oxygen on to the incandescent metal). Nor will the flight pitting of irons which have been observed to fall necessarily duplicate the features of the Henbury irons, which are known by their crater effects to have been of exceptionally high velocity.

R. BEDFORD.

Kyancutta Museum,
Kyancutta, South Australia.

---

[1] *Min. Mag.*, Sept. 1933, p. 390.

THE preservation of the fine series of material, now in the meteorite collection of the British Museum, from the meteorite craters recently discovered near Henbury in Central Australia is entirely due to the energy and enthusiasm of Mr. R. Bedford. This material, 1,000 lb. in weight, was collected by him, and he has given much thought and study to the matter on the spot. The numerous individual masses of meteoric iron show a considerable variety of surface forms and markings which are certainly puzzling. Some of them he admits are due to subaerial erosion and some to subterranean weathering. But others he believes are the original surfaces; that is, those resulting from the friction and burning of the meteorites during their brief flight through the earth s atmosphere This I concluded could not be the case for the following reasons

(1) None of the masses shows the thin jet black skin on smooth rounded surfaces characteristic of freshly fallen meteoric irons

(2) None of the polished and etched sections shows an exterior heating zone (with granulation, due to the transformation of α iron to γ iron at about 850° C)—proving that the masses are weathered remnants

(3) Some of the masses show various stages of breaking up, from the penetration of iron oxides along cracks to the detachment of flakes

(4) Iron shale of various types is found in large amount in close association with the meteoric irons, and has evidently been formed by the weathering of the masses

(5) Each crater must have been formed by the fall of a single large mass of iron, which became broken up by the force of the gaseous explosion If the meteorites had fallen as a shower of individuals of the sizes now found, they would have met with a relatively greater air resistance, and no crater would have been formed (Large meteoric stones are broken up in the air and fall as a shower without the formation of a crater)

The curious striæ and other markings on the surface of the 'slugs', commented on by Mr Bedford, may perhaps be explained by the weathering of strained and twisted metal These slugs' show a contortion of the lamellar crystalline structure, and they were evidently torn from the main mass by the force of the explosion

The British Coal-Tar Colour Industry

WHILST the original discovery of a coal tar dye was made by an Englishman, W H Perkin in 1856, and the early industrial development of the dyestuff industry took place in Great Britain, the rapidly growing industry soon found better conditions for its development in Germany The consequent decline of the British coal tar colour industry was already well marked in 1875, and in 1886 had proceeded so far that 90 per cent of the dyes then used in Britain were of foreign manufacture This condition of things persisted and, in the decade prior to the War, German domination of the industry was nearly complete

It is not an overstatement to say that the development of this highly scientific and extremely profitable industry in Germany instead of in Great Britain had enormous, if not decisive, political and economic effects both before and during the War It has also been an important factor in shaping the world conditions of the present day An immediate effect was that, in the very early days of the War, one of our great industries, that of the manufacture of textiles, which was of vast importance both on the military and civil fronts, was threatened with strangulation With the view of affording information regarding the origin and uses of dyestuffs, I published in 1915 a compilation of important addresses given on the subject papers published between Perkin's original discovery in 1856 and 1914 and papers published during the War period[1] On the publication of this book a letter was received from Sir John Brunner which contains a statement of his opinion that, with sufficient financial backing, the colour-manufacturing industry might have been developed here instead of in Germany

In view of the remarkable success of the firm of Brunner, Mond and Co , the considered opinion of Sir John Brunner on this point is of great historical interest and importance

The letter, which is published with the approval of Sir Felix Brunner, Bt , the grandson of Sir John, is subjoined

WALTER M GARDNER

Lawnhurst,
Didsbury,
Manchester

Silverlands,
Chertsey
Nov 7th, 15

Dear Mr Gardner,

I am greatly interested to read the advertisement of your new book on The British Coal Tar Industry"

When my brother Henry returned in 1857 from his studies at the Polyteckmkum at Zurich he entered the service of F Crace Calvert, who was then the public analyst of Manchester

He used to come home to my father's house at Everton every Saturday, and show us, from 1858 to the beginning of 1861, skeins of silk treated with aniline dyes that he had himself prepared

We were in our teens and we never got any farther than enjoying the colours

I have many a time reflected that if he and I had had the command of money, which came to us in later life, that the Coal Tar Industry would never have gone to Germany

Yours faithfully,
John Brunner

Technique of Height Measurement of the Ionosphere by the Pulse Method

IT has been shown[1] that in the pulse method of Breit and Tuve for the measurement of the heights of the regions in the upper atmosphere from which wireless waves are reflected, the quantity to be measured is the equivalent path $c\int ds/U$, where U is the group velocity along an element of path ds and c is the velocity of light The group velocity U is, by definition, the velocity of the crest of the disturbance Now the crest is by no means an obvious point in the photographic registration, and it has been usual therefore to refer measurements to the beginning of the pulse A great deal of ingenuity has been called forth in making this point readily recognisable, by shortening the pulse, increasing the rate of build up, etc , so that errors due to variation in amplitude may be reduced to a minimum. Errors due to dispersion have been ignored or accepted as inevitable

Since the crest is the point of greatest importance it must be *made* obvious Consider the pulse shown in Fig 1 (*a*); there is no point on the curve that is obviously defined But if we differentiate it we obtain the curve of Fig 1 (*b*) and we see that three points, corresponding to the beginning, crest and end of the pulse, are clearly indicated, for they cut the zero line at an angle and this angle can be made as large as we please by increasing the amplitude If we differentiate a second time obtaining the curve of Fig 1 (c), we define the beginning and end still more accurately since there are discontinuities at these points and we also define the points of inflexion of the original curve So that first, we can readily measure the quantity we wish to measure and secondly, we have four other points available for the measurement of distortion or of dispersion of the pulse

---

[1] The British Coal Tar Colour Industry its Origin, Development and Decline By Walter M Gardner Pp 487 London, 1915 Williams and Norgate

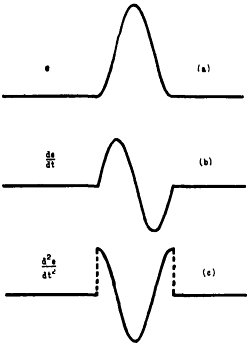

FIG 1

The differentiation of such a pulse is an operation which can be performed very simply by an electrical circuit and all that is necessary is to connect a large capacitive impedance in series with a relatively small resistance across the output of the receiver normally used for echo delineation, to amplify the voltage across the resistance and to apply the output from this amplifier to the cathode ray oscillograph in place of the receiver output A second capacitance resistance potentiometer across the output of the amplifier will give the second differential of the pulse

The use of the differential curve in place of the pulse itself results in a number of practical advantages, quite apart from those already mentioned When taking continuous records of heights with either time or frequency as the second variable it is customary to select a strip of the echo pattern by means of a narrow slit, in all the systems in use, disturbances, such as noise, decrease the contrast between the trace and the background, whereas by using the differential curve the definition of the trace indicating the peak of the pulse is practically constant, though that of the beginning and end are affected as before The band width of the component frequencies of the pulse indicated above is quite restricted compared with that necessary for the same accuracy of measurement by the usual method, for there are no abrupt changes in the rate of increase of amplitude it can be shown that heights greater than about 100 km can be measured to an accuracy better than 1 per cent using a band width of only 1 kc/s this incidentally resulting in a considerable increase in the signal/noise ratio If we require resolution better than 100 km, we are forced to use band widths correspondingly wider the actual resolution being inversely proportional to the band width By using the differential curve in place of the pulse proper the resolution is increased twofold and if the second differential is used and the pulse is symmetrical we have a further twofold gain the above follows directly from a consideration of overlapping pulses The technical difficulties of producing such a pulse are not at all serious Finally in those cases where a common control frequency is not available at transmitter and receiver and a self synchronising scheme has to be devised it becomes feasible to use the ground ray to start the time base In such cases though a portion of the up stroke may be missing the important part the peak, can be made to occur on the time base so that no loss of accuracy results

Fig 2 shows a record taken at these Laboratories using a differential curve in place of the pulse itself The beginning of the ground ray is not visible for a pulse tripped time base as mentioned above is in use At the lower edge of the record is the fine black line defining the peak and just above it the edge defining the end of the ground ray Along the middle of the record runs the trace of an echo reflected from the Appleton region at a height of 300 km and the central line corresponding to the peak is clearly defined For recording the base line only of the echo pattern is visible as in the method described by Builder[2] Note that the same definition of the central line could be maintained for a height scale some 5–10 times as great so that measurements to an accuracy much better than 1 per cent should be attainable though light intensity considerations may then become the limiting factors The echo recorded was a very simple one but even if it should be complex we record more information with greater accuracy by this method than by direct pulse delineation

Apparent Clustering of Galaxies

A CONSIDERABLE amount of material on the distribution of external galaxies has become available through the publication of the Harvard and Mount Wilson surveys Shapley and Hubble have both discussed the observed irregularities in the distribution of these galaxies Shapley emphasises the non uniformity of the distribution of matter in the metagalaxy Hubble finds that statistically uniform distribution of nebulæ appears to be a general characteristic of the observable region as a whole , and hesitates to admit the reality of clusters or groups of galaxies with the exception of the few that are readily recognised as such Statistical analysis of the available material is now possible , and as the comparison between the observed distribution curves corrected for the effect of dispersion in the limiting magnitudes and the theoretical frequency curves computed on the assumption of random distribution has yielded some rather definite results it seems worth while to communicate them in advance of publication in more detail

The Shapley Ames catalogue of galaxies brighter than the thirteenth magnitude[1] exhibits conspicuous deviations from a random distribution Both galactic polar caps were divided into a number of equal areas (well known clusters being excluded) and the number of galaxies was counted in each area The observed frequency curve had a much larger dispersion than the theoretical curve computed on the assumption of random distribution The accompanying table shows conclusively that the irregularities in the distribution cannot have been caused by galactic or extragalactic absorption

North Galactic Polar Cap

No of galaxies (Shapley Ames)	$\overline{\log N}$ (Hubble)	No of galaxies (Shapley Ames)	$\overline{\log N}$ (Hubble)
½	1 92	15	1 79
1½	1 99	17	1 85
4	1 86	18½	1 87
5½	1 90	22	1 96
6½	1 88	24	1 95
10	1 87	26	1 87
10½	1 88	29½	1 86
12½	1 87	31	1 88
14	1 83	31½	1 86
14½	1 95	36	1 94
14½	1 93		

The first column of this table gives the number of galaxies counted for one of the areas in the Shapley Ames catalogue The centres of 9 13 survey fields used by Hubble in his study of the distribution of faint galaxies (down to mag 19 5) fall within the limits of each area and the second column of the table contains the mean value of log N for these faint galaxies The absence of any progression in the values of $\overline{\log N}$ shows that the deviations from random distribution are due to a real clustering of galaxies and are not caused by the absorption of light in space

Both the Mount Wilson[2] and Harvard[3] surveys of faint galaxies show evidence of clustering The diagram (Fig 1) gives a comparison between Hubble's observed distribution curve (dots), corrected for a dispersion of ±0 15 mag in the limiting magnitude of the Mount Wilson plates and the theoretical curve (crosses) computed on the assumption that the galaxies are distributed at random

Similar deviations from random distribution are found in the Harvard material The observed frequency curve in log N has for the north galactic polar cap a dispersion of $\pm 0\ 25$ and as the maximum value of the error dispersion amounts to only $\pm 0\ 15$ (most probable value $\pm 0\ 09$) the true dispersion must be of the order of $\pm 0\ 20$ in log N The dispersion computed theoretically for random distribution is not larger than $\pm 0\ 03$ in log N For the south galactic polar cap the discrepancy is even greater We should in addition consider Shapley's elegant and definite proof for the presence of clustering in nine regions[4]

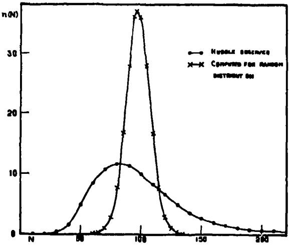

FIG 1

We can scarcely escape the conclusion that a widespread tendency towards clustering among galaxies is one of the chief characteristics of our universe

An Arithmetical Prodigy in Egypt

A BOY of unusual arithmetical ability named Mohammed Ismail Turki El Attar has recently died in a Government asylum in Cairo He was the son of a grocer in a small country village near Teh el Barud in the Delta and when first discovered used to make a precarious living by exhibiting his powers as a calculator in cafés in Cairo He was unable to read or write and was obviously a boy of poor general intelligence His powers were tested on various occasions The following is a summary of some of the calculations he performed mentally

The squares of numbers of two digits were given correctly almost instantaneously, but there was occasionally hesitation in giving the products of pairs of two digit numbers Products and squares of 3 digit numbers were given in times varying from eight to forty five seconds Cubes of 2 digit numbers were worked out in from two to three minutes while the product of two numbers of 10 digits was worked out correctly in twenty minutes

8^{16} was correctly computed in five minutes, 5^{10} in twenty seconds and 6^{10} in seventy seconds.

Division was a slower process and 9 digits divided by 3 took times varying from two and a half to seven and three quarters minutes.

Square roots of 6 digit numbers were extracted in less than a minute while cube roots took longer. Curiously enough, the memorising of a number of 27 digits was not done successfully, although he could repeat questions which had been put to him and their answers after some days had elapsed and would break off calculations in the middle to ask for milk or cigarettes, taking up the calculations again where he had broken off. His methods of working were not discovered but he had obviously memorised the squares of two digit numbers, and less completely the products of two digit numbers.

Though the arithmetical powers of this boy were surprising, they were not comparable with those of some of the calculating prodigies described by Rouse Ball in Mathematical Recreations and Essays.

The boy was a good illustration of cases of arrest of mental development in which normal or even phenomenal mental capacity is observed in certain limited directions such as memory, calculating ability, musical ability, etc. He was so defective in respect to other mental faculties that he was unable to adjust himself to ordinary conditions of life and became an inmate of the mental hospital.

He died in the hospital at nineteen years of age. The autopsy disclosed that he had a softened patch, probably an old hæmorrhage, in the right occipital region of the brain, about the size of a small hen's egg. A recent hæmorrhage at the same place of the brain was the cause of his death.

Determination of Sex

THOSE who are interested in the heredity of sex will be grateful to Prof. MacBride for again exposing *in these columns*[1] the *naïveté* of some early views of this problem (which he attributes to Morgan). Especially will they be reassured by his conclusion. He points out that sex is essentially the same thing wherever it occurs. He concludes — "It seems clear that there are fundamentally *opposed* male and female constitutions, but that the constitution of every individual is a mixture of the two, and that the structural manifestations of sex depend on the *proportion* of these constitutions and on which gains the upper hand in development" (italics mine).

This view is somewhat similar to that reached by way of experimental genetics. Thus Goldschmidt, reviewing his experiments since 1910[2], states that "the resulting sex is dependent upon two genetic somethings, one of which shifts sex towards the female, the other towards the male side". Again, Morgan's colleague Bridges[3] says that 'both sexes are due to the action of *opposed* sets of genes, one set tending to produce the characters called female, and the other to produce the characters called male. These two sets of genes are not equally effective, for in the complement as a whole the female tendency genes outweigh the male tendency genes and the diploid (or triploid) form is a female. When the *relative number* of the female tendency genes is lowered by the absence of one X, the male tendency genes outweigh the female and the result is the normal haplo X male."

Thus, as my italics show, the experimental geneticist seems to agree with what Prof. MacBride has expressed in more generally intelligible language, not only in admitting the essential sameness of sex in all organisms but also in understanding the function of proportion in its determination in some of them. Unanimity among the different branches of biology has therefore been reached after a long period of divergence from entirely different data and, what is more, apparently unawares. Such an event, surely, should not be allowed to pass without notice and without applause. The usual view that the chromosome theory of sex determination criticised by MacBride was a special hypothesis put forward by McClung in 1902[4] and therefore not attributable to Morgan, who accepted the hypothesis only in 1911[5], should perhaps also not pass without mention.

I AM delighted to find that such a distinguished cytologist as Dr. Darlington, though a long compass round be fetched, has arrived at somewhat similar conclusions to those to which I myself have been led respecting the nature of sex. I do not, of course, view the gene in the same light as he does; but since in an article shortly to be published in NATURE I have given my views as to the nature of the gene, Dr. Darlington and I need not quarrel about the matter now.

Ergine

RECENTLY we showed[1] that the four ergot alkaloids (ergotoxine, ergotinine, ergotamine and ergotaminine) by treatment with alcoholic potassium hydroxide give rise to a crystalline base ergine, which constitutes about half the parent molecule.

We have since proved that ergine is the amide of an acid $C_{15}H_{15}N_2 \cdot COOH$ and further analyses of ergine and its salts show that the formula for ergine requires correction to $C_{16}H_{17}ON_3$, in agreement with the formula for the acid now isolated.

Jacobs and Craig have published a paper[2], in which they have described the action of alkali upon ergotinine and the isolation of a crystalline acid, $C_{16}H_{16}O_2N_2$, which they name lysergic acid. We have no doubt that this is identical with that prepared by ourselves from ergine.

Research Items

Neolithic Age in Western Europe Recent interpretation of archæological evidence has shown an increasing tendency to reduce the duration of the neolithic age as against the claims of the mesolithic and bronze ages, until, as a period, it has seemed in danger of extinction In Britain, recent researches notably the pottery analyses of Mr Stuart Piggott, have placed the neolithic on a more assured basis, and a similar service is performed for the neolithic and chalcolithic periods of western Europe in *Antiquity* of March by Jacquetta Hawkes As a starting point is taken an early culture which is identified in south and east France It passed, presumably up the Rhone Valley, to the western Swiss lakes, where it became established in the first Danubian period Thence it passes to Britain without touching Brittany It is not yet possible to determine the exact limits of distribution of this culture In the next phase, a period of differentiation one offshoot, coming under Danubian influence, forms the Michelsburg culture, while another branch, spreading westward, joins with an influence from southern France producing a more sophisticated type of pottery and is responsible for the Chassey culture This spreads farther westward and joins with other elements to produce the elaborate chalcolithic culture of Brittany Cutting across this western culture from Belgium to the Channel Islands is the Seine Oise Marne culture, of which the most characteristic feature is the vase with everted rim well marked shoulders and splayed foot The pottery of this last named culture, it has been suggested shows a relationship with that of the peoples who in the meanwhile and after severe flooding had resettled the western Swiss lakes their culture showing affinities with that of their predecessors but developing new features

Birds' Bones from Prehistoric Eskimo Ruins On St Lawrence Island in the Bering Sea Eskimo habitations dating from more than 2 500 years ago to village sites of half a century back have been excavated during several seasons, and several thousand bones of birds have been found amongst the food refuse In all, 45 species were represented, ten of them new to the fauna of the island (H Friedmann, *J Washington Acad Sci* **24**, 83, Feb 1934) Commonest in all sites of all ages (found in 69 diggings) was Pallas's murre (*Uria lomvia arra*), still the most abundant bird on the island The other birds generally used for food included the crested and paroquet auklets, the Pacific and king eiders, the latter more common than the former in the older diggings, contrary to their relative abundance to day, and, curiously enough, the pelagic cormorant (*Phalacrocorax pelagicus*), represented from the most ancient to the most recent site Other pelagic birds include fulmars, shearwaters and the short tailed albatross Considering the difficulty of obtaining such birds, it seems strange that birds so large and so abundant on St Lawrence Island as geese should be poorly represented, the more so as geese are now much hunted for food by the Eskimos

Transposed Hinge Structures in Lamellibranchs. Under this title, W P Popenhoe and W A Findlay describe several cases of valves with the hinge elements *reversed, those normally occurring in the right being* found in the left valve, either wholly or partially (*Trans San Diego Soc Nat Hist*, **7**, No 26, 1933) The relations of the individual teeth to one another, and to the bilaterally symmetrical parts of the shell, are exactly similar to the relationships which are present in the normal individual The shells in question belong to the genera *Venericardia*, *Astarte*, *Transennella* and *Unio* Many other genera were examined, chiefly venerids and tellinids, but out of 2,000 no reversed specimens were seen The dentition in these abnormal forms may be completely or partially transposed but no complete transposition involving cardinals, anterior and posterior laterals has been found in this study The tendency is for the cardinals and anterior laterals to transpose together The posterior laterals, which are formed independently of the others, do not usually transpose In rare cases the posterior laterals transpose and not the cardinals This hinge transposition has usually been regarded as a very rare phenomenon, even rarer than the comparable abnormality of inverse coiling in gastropods but these notes show *that it takes place quite as frequently* as in *some of* the helices in which reversal is much easier to see The authors are of the opinion that the abnormal hinges described represent examples of a systematic abnormality, *not pathogenic except in very rare cases*, in which certain of the primary lamellæ from which hinge teeth are derived have developed in the opposite valve from that in which they are normally found

Atomic Composition of Plants in Relation to Atomic Number Summarising the results of large numbers of analyses, Vinogradov (*C R Acad Sci*, **197**, 1673, 1933) claims that the relative number of atoms of any chemical element present in living matter tends to be inversely proportional to the atomic number of that element The curves showing this relation also tend to show a regular periodicity Maxima occur, for example at atomic numbers of 18 36 54, 72 and 90 and special significance is claimed for the elements found at these and at other periods It may be noted that no biological function is at present known for most of these significant elements

Replacement of a Bud by Roots Mr Samuel Sandison writes from the Department of Botany, University College, Dundee to report a striking case noted during some observations upon the propagation of *Forsythia suspensa* by cuttings Usually roots arise from buds at the basal end of the cuttings and always from the basal half of the bud In this case when the bud scales were stripped off, the bud apex had disappeared and in its place five roots were seen arising from a common point of origin, somewhere about the original base of the bud

Pigment of *Aspergillus* Spores Further results of his investigations on aspergillin, the brownish black pigment of the spores of *Aspergillus niger*, have been recorded by Dr Adolfo Quilico in *Rend R Ist Lombardo Sci Let*, Parts 11–15, 1933 This pigment exhibits an acid character, which is ascribed to the presence in its molecule, not only of phenolic hydroxyl groups, but also of carboxyl groups It is, indeed, able to displace carbon dioxide from alkali and alkaline-earth carbonates, and, when heated to

150°–250° C, it liberates appreciable amounts of carbon dioxide and water, at the same time losing its solubility in alkalis When oxidised by hydrogen peroxide, it yields, together with acid products not yet characterised, mainly mellitic acid, which is also formed, along with a small amount of oxalic acid, on oxidation with nitric acid Consideration of the chemical behaviour indicates that aspergillin is a typical humic acid, analogous to that extractable from peat, lignite and soil This is the first known case of the formation of a humus substance in a vegetable organism from a carbohydrate such as sucrose, and is of interest as a contribution to the problem of the genesis of humic matters Unlike peat, etc, the *Aspergillus* spores yield a particularly pure humic acid, which lends itself well to chemical investigation

Scolt Head Island A study of the physical processes at work on the north coast of Norfolk has led to some interesting conclusions with regard to this island, which lies to the east of Brancaster In a lecture to the Royal Geographical Society on March 12, Mr J A Steers discussed the relative effects of tidal and wave action on this coast The island apparently began by wave action separating the shingle from the sand on an extensive foreshore, a stage that can be seen at other places on that coast A shingle ridge near high water mark formed an off shore bar, became more stable, extended westward by wave action and formed a recurved end Dunes formed on its surface Newer ridges were added by wave action to the main ridge and pushed backwards, a process that can still be seen in action At other times the new ridges were of sufficient size to form permanent additions to the island The island lies not parallel with but at a slight angle to the coast Wave action would tend to build at right angles to the coast line, but this would force the distal end into deep water and so subject it to greater wave action, which necessarily drives it back The island is about four miles long, with a width that varies with the state of the tide The dunes show various stages of consolidation, and between them lie salt marshes which increase in height from the younger in the west to the older in the east

The Constant Pressure Air Thermometer A number of careful determinations of the volume coefficients of condensable gases have been made by Coppock and Whytlaw Gray using the Callendar compensated thermometer (*Proc Roy Soc*, A, Feb) The gases used were ethylene, air, carbon dioxide, dimethyl ether, nitric oxide, carbon monoxide and sulphur hexafluoride, under pressures up to 1 metre of mercury The gases were carefully purified and butyl phthalate was used as a manometer liquid The values obtained with a glass bulb, when extrapolated to zero pressure, gave values for the coefficient layer, then the perfect gas' value, and this was ascribed to adsorbed gases on the walls of the vessel These are liberated as the temperature rises and give values for the coefficient which are too high The difference was less marked for a fused silica containing bulb, and the authors suggest that silica is a suitable material to adopt as a standard in determining the volume coefficient for condensable gases

Positive Electrons from Lead ejected by γ-Rays In a communication which was unfortunately too long for use in our correspondence columns, but will, we hope, shortly be published elsewhere, Dr A Alichanow, of the Physical Technical Institute, Leningrad, describes measurements of the velocity distribution of the positive electrons ejected from lead by the γ rays of radium C′ A semicircular focusing apparatus was used, and the electrons were detected by coincidence counts in two contiguous Geiger Muller counters Two pronounced and two subsidiary maxima were found in the distribution curve which appear to agree well with the known γ rays of energy greater than 1 78 × 10⁶ volts Similar measurements were also carried out with a source of radon enclosed in a thin glass tube, and also in this case positive electrons were found with a somewhat similar velocity spectrum The total number of the positive electrons in the latter case is 0 5–1 per cent of the number of β rays of the corresponding continuous spectrum This is in agreement with the measurements of Dr Skobeltzyn, whose experiments are described in a letter in this issue of NATURE (p 565), where he points out the problems raised by this result

Isotopes of Hydrogen In three preliminary notes in the *Proceedings of the Royal Academy of Sciences of Amsterdam* (36, Nos 6 and 7, 1933, 37, No 1, 1934) Zeeman and de Gier reproduce very clear parabolic traces obtained by the use of the J J Thomson mass spectrograph with gases containing hydrogen isotopes and inert gases Curves were obtained which could be interpreted as belonging to hydrides of the inert gases since they do not exhibit multiple charges Various kinds of ions were detected $(H_2^1H^2)^+$, $(H^1H_2^2)^+$, $(H_3^2)^+$, and others due to traces of impurities in the apparatus The mass differences between He and $H_2^1H^2$, HeH^1 and $H_1H_2^2$, $HeH^2{+}$ and $H_2^2{+}$ were measured with some accuracy In an experiment with hydrogen obtained by passing water vapour over sodium, a faint parabola with $m/e = 4$ was obtained after an exposure of half an hour, and the hydrogen isotope was thus detected without previous concentration

Structure of some Platinum and Palladium Compounds. Chemical and X ray experiments by Cox Saenger and Wardlaw (*J Chem Soc*, 182, 1933) with the dimethyl sulphide derivatives of platinous and palladous chlorides, $[Pt(Me_2S)_2Cl_2]$ and $[Pd(Me_2S)_2Cl_2]$, indicate that the two isomeric forms of the former are planar *cis trans* compounds The α form is the *trans* compound, not the *cis* compound as was suspected by Werner, or a tetrahedral configuration as suggested by others The results with the β isomer are less definite, but it seems likely that the sulphur atoms are in *cis* positions and that the compound is ionised in the solid state In the case of the palladous compound, only one form was obtained, which is isomorphous with the α platinous compound and is therefore no doubt the plane *trans* compound The chemical reactions of the substances differ very considerably, particularly with silver oxide The β platinous compound reacts rapidly with silver oxide with production of silver chloride and a basic substance, which forms an alkaline solution in water and reproduces the original compound with acid The α form, on the other hand, reacts only slowly, with evolution of dimethyl sulphide and precipitation of platinum, as hydroxide or oxide A so called third form of $Pt(Me_2S)_2Cl_2$ had been shown by Tschugaev and co workers to be really the plato salt, $[Pt(Me_2S)_4]$ $[PtCl_4]$, a result confirmed by the present investigators

Ground Levels in Bihar in relation to the Earthquake of January 15, 1934

By Col Sir Sidney Burrard, Bt, F R S

IN an article published in Nature of February 17, p 236, Dr de Graaff Hunter has endeavoured to show that the surface of the plains where the earthquake of January 15 occurred in India had been proved by levelling to have been rising in height throughout the present age, at the rate of 4½ ft per century This conclusion is so important that I feel justified in submitting my reasons for questioning it Dr Hunter bases his theory on the results of levelling but these are not confirmed by the geographical facts of Bihar The accuracy of levelling is estimated from the agreement between two independent levellers Although they take independent observations, they work together and there are sources of error which affect them both

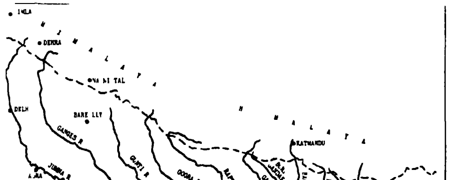

Fig 1 Rivers of Bihar

The history of levelling has placed on record several examples in Egypt, India and France of errors being accumulated and being only discovered when the levelling was connected with mean sea level We have no mean sea level in Bihar, and the only check here upon levelling errors is provided by the rivers (Fig 1) The numerous rivers that traverse the flat plains are governed, like sea level, by gravitation The surface of the plains differs in form from that of the sea, in that they have a gentle slope from north to south and a still gentler slope from west to east The combination of these two slopes compels the numerous rivers, as soon as they escape from the Himalaya, to follow courses that converge upon the south east corner of Bihar It is perhaps not strictly correct to say that the slopes determine the courses of the rivers, for the rivers have created the slopes If Bihar were at sea level, its surface would be spheroidal, but as it is raised above the sea by two hundred feet of unconsolidated alluvium, the rivers have so shaped its surface that they may reach the sea along curves of least resistance The adjustment of the surface to the rivers is very delicate, and it is not possible to say that either is the governing factor their co operation is perfect

The rivers have to carry immense volumes of water from the Himalayan snows across densely inhabited level plains, and although they have the guidance of skilled engineers, a constant rise of the ground level across their paths would upset their balance and deflect their courses No such results have been observed in confirmation of the levelling theory

It may even be doubted whether a flat surface overlying alluvial depths could possibly be raised 4½ ft per century as the levelling theory assumes If any area of alluvium were to be raised above the normal level of the surface, or above the normal saturation level the rise would probably be converted into blown sand', and would be removed by winds

Dr Hunter s conclusion that the surface of the earthquake area has been rising 4½ ft a century is based upon three levelling results — Pirpainti, Benares and Dinajpur

Pirpainti Levelling A discrepancy of 3 178 feet was discovered at Pirpainti, when in 1929 a new line of levels intersected the old line of 1862 Dr Hunter believes that this levelling discrepancy of 3 178 feet denotes a rise in the height of Pirpainti between 1862 and 1929 I find it difficult to place such faith in the accuracy of this levelling Pirpainti is a station of the East India Railway the levelling along this railway was carried out in 1862, the levellers were inexperienced, their instruments were primitive When the bench mark was originally cut at Pirpainti station, it was not intended to be a standard datum for scientific observations No pendulum observer would take observations in this railway station I feel that the discrepancy of 3 178 feet at Pirpainti may be due to an accumulation of errors arising from the instability of the site, from the inexperience of the levellers in 1862, and from the secondary' character of the check levelling in 1929

Benares Levelling A discrepancy of 2 170 feet was discovered at Benares when in 1916 a new line of levelling intersected the old line of 1863 This discrepancy is attributed by Dr Hunter to the rise of Benares between 1863 and 1916 The levelling in 1863 to Benares was a continuation of the Pirpainti line, and its result is dependent on Pirpainti The levelling of 1916, which first disclosed the discrepancy of 2 170 feet at Benares, was brought from Calcutta across the mountainous region of Hazaribagh This levelling was carefully observed but no levelling over mountains can have a high degree of accuracy The rays to the fore and aft staves are exposed to unequal refraction I do not think that the level of the flat plains of Bihar can be tested by mountain levelling A bench mark on Hazaribagh rock would be a reliable standard datum for Bihar, provided it were not high up but on a steep ascent levelling accuracy deteriorates

Dinajpur Levelling In 1900 (after the publication by the Geological Survey of the memoir on the great earthquake of 1897) a line of levels was carried across Bengal from south to north from Calcutta to Dinajpur by Capt H I Crosthwait and Lieut H M Cowie this line was in every way scientific and the height of Dinajpur was determined as accurately as was possible In 1925 a new line of levels intersected the 1900 line at Dinajpur The discrepancy between the 1900 and the 1925 results was 0 963 foot

Dr Hunter assumes this discrepancy of 0 963 foot to be due to the rise of Bengal between 1900 and 1925 and he converts the observed error of 0 963 into a theoretical rise of 4 feet in 100 years Dr Hunter s procedure is based upon the assumption that there was no levelling error on either of the lines that met at Dinajpur Such an assumption is contrary to experience If we bear in mind that the 1925 level line had to pass through the streets of Calcutta and to cross the Hugli and that both the 1900 and 1925 lines had to cross the main stream of the Ganges we may feel justified in thinking that a discrepancy of 0 963 foot in 500 miles is within the limits of accumulated error

The safest way of proving whether Dinajpur has risen in height would be to re observe the whole levelling line of 1900 bench mark by bench mark from Calcutta to Dinajpur A single intersection of this line by another line does not furnish convincing evidence

---

By Dr J de Graaff Hunter C I E

My short account of the results of spirit levelling in Bengal accumulated between 1862 and 1930 and their interpretation are given in the Survey of India Geodetic Report (6 104–6) In such a report considerations of space preclude the inclusion of every corroborative detail which the full records of the work contain

Sir Sidney Burrard not quite rightly says that my theory rests on three levelling results Actually it rests on a group of levelling circuits all giving evidence in the same direction , but the results which he cites are certainly important The first of these does not rest on the single bench mark at the railway station If reference is made to pp 71 97 *loc cit* it will be seen that two bench marks a quarter of a mile apart, were picked up at Pirpainti and gave results agreeing within 0 05 ft Further the connexion with Pirpainti was made after results at Bhagalpur and Luckeesarai had indicated a rise of more than two feet , which the Pirpainti connexion confirmed The secondary' levelling of 1929 is almost of the same type as what was formerly (before the introduction of levelling of high precision) known as levelling of precision

The Benares result depends in part on Pirpainti now justified, and on modern levelling through the mountainous region of Hazaribagh In the case of a much more mountainous Himalayan circuit, I investigated the refraction anomaly and found it to be trivial a much more important error being due to the variation in length of the wooden levelling staves during the course of the day This tends to increase with the total amount of ups and downs of the line which in the case of the Hazaribagh line are not enough to justify rejection of results though nowadays we should employ invar staves in such a case

Careful consideration was given to the errors which might naturally be expected in all these levelling lines including those on which the Dinajpur result was based and the special difficulties of wide river crossings were not forgotten

The geographical evidence is sufficient to cause Sir Sidney to mistrust the levelling of 1862 because the workers were inexperienced and had primitive instruments and more modern work when it passes through mountains such as occur in Hazaribagh I cannot bring myself to discount all the spirit levelling in this way and prefer to judge it by its own internal and unbiased evidence not omitting to consider the systematic error as usually evaluated

The spirit levelling evidence is limited to the area of its observations and so gives only a partial picture This covers roughly the triangle Calcutta–Darjeeling–Benares So the contours of my chart (NATURE Feb 17 p 236) extend little into the area of Sir Sidney s sketch of the rivers of Bihar Most of this river area may have risen almost uniformly which would certainly be in keeping with my area of underloading Why then should extensive geographical changes be expected or their absence be regarded as in opposition to the results of much spirit levelling ?

In my opinion much of the so called systematic error in levelling must be due to secular changes of ground level operating during the progress of the lines forming a circuit On this account we are probably assessing the precision of spirit levelling below its true value

---

Research in the Sea*

THE latest available issue of the *Journal of the Marine Biological Association* contains many valuable memoirs being records of research undertaken chiefly at the Plymouth Marine Laboratory but also at the Scottish Marine Station Millport the Port Erin Marine Station Isle of Man and the Dove Marine Laboratory Cullercoats Northumberland The whole is admirably planned and emphasises the fact that oceanography in its broadest sense is the object of all the work done in these laboratories that is to say the study of the sea and its contents both animate and inanimate and of all factors which influence these centring round the fish itself It is impossible nowadays to separate pure science from the practical side or to say that any matter connected with the sea is irrelevant to its study and we find these researches carried on in the marine laboratories of Great Britain tend more and more to fit into one another and show real progress in general knowledge of the interpretations of marine phenomena

A glance at the subject matter will show how varied are the contents but yet how well everything really hangs together Perhaps the most notable of the contributions is Mr E Ford's account of the herring investigations conducted at Plymouth during the years 1924–1933, which is a summary of his own work in connexion with the Plymouth herrings covering this period He shows how far we have now gone in elucidating herring problems—a considerable distance, for we now can predict fairly well the probable constituents of the main portion of the herring fishery some years ahead, although weather and other agents may always upset calculations The breeding of the herring is now becoming well understood where the eggs are deposited, where the newly hatched larvæ are to be found and those slightly older, their migrations out to sea in search of food and their spawning migrations inshore Intensive studies of bones show how temperature has a distinct influence on the number of vertebræ and therefore of size, and thus the problem of races may be interpreted, and the reading of the scales tells us the ages of the fishes and the year classes to which they belong, so that we may know what classes are likely to make up the fisheries of future years This full and valuable paper is indeed worth reading

---

* *Journal of the Marine Biological Association* N S 19 No 1 August 1933 pp 1 286 (Plymouth The Association)

Mr G A Steven's account of the food of the shags and cormorants round the Cornish coast also appeals directly to the fishing industry Here a long standing error is corrected, showing that the shag, which is far commoner on the open coast than the cormorant, is innocent of the destruction of commercially important fishes, its main food being smaller fishes of little value and usually not consumed by man The cormorant, feeding much farther inland, certainly does considerable damage by preying on our edible fishes, especially flat fishes

Trematode parasites of fishes are dealt with by Mr E Idris Jones, and Miss D Atkins describes a very interesting new orthonectid in the bivalve mollusc *Heteranomia* showing quite new features

The shell fish industry is represented by an important paper on oysters by Prof J H Orton, following up his previous work on sex, showing the fate of unspawned ova and the change from male to female The results described here of years of experiment with oysters in cages prove definitely for the first time that male individuals of *Ostrea edulis*, our common commercial oyster, pass into the female condition in significant proportion within twelve months, and that greater proportions attain the female condition in two years

Information as to the food of fishes and of invertebrates is at all times desirable, and on this subject there are several papers dealing with the plankton, Mr F S Russell on the seasonal distribution of macroplankton, Miss O Jorgensen on the marine *Cladocera* of the Northumberland plankton, and three papers of great interest by Dr A G Nicholls and Miss S M Marshall on *Calanus finmarchicus* from the Clyde area In these last the copepod, which is of the greatest significance as fish food, especially of the herring, is dealt with in a masterly way, and its reproduction and seasonal distribution, its variation in size and its vertical and diurnal migrations are described Mr G N Spooner's experiments on the reaction of marine plankton to light are very suggestive and may lead to the elucidation of some of the difficult problems connected with migrations

From animal plankton we come to vegetable plankton, and find Mr H W Harvey's paper on the rate of diatom growth, showing how the neritic diatom *Nitzschia closterum*, taken from the pure cultures grown by Dr E J Allen continuously for many years, react to experimental conditions, and Mr F M Ghazzawi, on the littoral diatoms of the Liverpool and Port Erin shores, touches a section of those Algæ which has been too long neglected and is of considerable importance in the economy of the sea

In connexion with the long standing and classic Mendelian work on *Gammarus* by Mrs E W Sexton, which has been going on for many years in the Plymouth Laboratory, it is interesting to find that Mr Bassindale has discovered abnormal eyes in wild *Gammarus* in the Tay Estuary

The inorganic element is well to the fore, and in two papers Dr L H N Cooper continues his work on chemical constituents of biological importance in the English Channel and shows how winds influence the salt content in the sea, whilst Dr W R G Atkins and Dr H H Poole discuss the use of cuprous oxide and other rectifier photo-cells in submarine photometry, and Dr Atkins describes a method for rapid estimation of the copper content of sea water.

University and Educational Intelligence

A MATHEMATICAL Colloquium will be held in St Andrews on July 18–28, under the auspices of the Edinburgh Mathematical Society Courses of lectures will be given by Prof E A Milne (Oxford), Prof B M Wilson (Dundee), Prof H W Turnbull (St Andrews), and Mr W L Ferrar (Oxford) The local secretary is Dr D E Rutherford, United College, St Andrews

THE educational film has now an assured place as a teacher's tool The Central Information Bureau for Educational Films, established to further its employment, publishes a bulletin, *Film Progress*, in the December–January issue of which is announced the completion of a catalogue (price 3*s* 9*d*, post free, Central Information Bureau for Educational Films, 103 Kingsway, W C 2) of about two thousand films (35 mm, 16 mm and 9 5 mm) already made and approved by authoritative associations or individual experts on agriculture, engineering and industry, geography and travel, vocational guidance, and science, including hygiene, physics, chemistry, geology, physiology and psychology

WE have received from the University of Leeds a handsomely illustrated booklet presenting the salient features of its organisation, actual and projected, and an account of its chief courses of study It recalls the fact that the land and buildings of the University have been provided almost entirely as a result of private generosity, sometimes unsolicited and sometimes in response to public appeals such as that which has recently produced £430,000 Unshackled by commitments of imperfectly prescient founders of long ago, the University is taking shape in the disposition of its main buildings as an example of planning for maximum efficiency, the departments comprised in the faculties of arts, law, economics and commerce, science and technology being grouped around the new Brotherton library and within five minutes' walk of the medical and dental schools, which are adjacent to the General Infirmary Attention is directed to the fact that more than a quarter of the full time students are in halls of residence

Science News a Century Ago

Mary Somerville at the University of Cambridge

In the spring of 1834 Dr William Whewell sent an official invitation to Dr Somerville and his wife Mary Somerville the distinguished author of the Mechanism of the Heavens to visit the University of Cambridge for a week or so Apartments had been arranged for them in Trinity College Prof Adam Sedgwick the geologist was entrusted with the social arrangements and general itinerary In a letter to Dr Somerville dated April 1834 Sedgwick in characteristic vein says —

My dear Somerville your letter delighted us I have ordered dinner on Thursday at 6½ and shall have a small party to welcome you and Mrs Somerville On Tuesday you will I hope dine with Peacock, on Wednesday with Whewell on Thursday at the Observatory For Friday Dr Clarke our professor of anatomy puts in a claim For the other days of your visit ample employment A four poster bed (a thing utterly out of our regular monastic system) will rear its head for you, and Madame in the chambers immediately below my own and your handmaid may safely rest her bones in a small inner chamber Should Sheepshanks return we can stuff him into a lumber room of the Observatory but of this there is no fear as I have written to him on the subject and he has no immediate intention of returning You will of course drive to the great gate of Trinity College and my servant will be in waiting at the Porter s lodge to show you the way to your academic residence We have no cannons at Trinity College otherwise we would fire a salute on your entry we will however give you the warmest welcome we can (Personal Recollections of Mary Somerville by her daughter Martha Somerville (1873))

American Railroad Progress

The first American railroad to be constructed with the intention of using steam locomotion only was the South Carolina Railroad commenced in 1827 but the first to be opened was the Baltimore and Ohio Railroad a part of which was brought into service in 1830 Peter Cooper s *Tom Thumb* engine running for a short time With the adoption of British practice and the importation of English locomotives which were far better than the early American locomotives railroad projects created increased interest and by the spring of 1834 there were no fewer than thirty seven incorporated railroad companies in the State of New York alone having a total capital of nearly thirty million dollars As in England the construction of the permanent way presented many difficulties and when the Philadelphia and Columbia railroad was built three different systems were tried On one part of the line the rails were laid on continuous granite sills on another on stone blocks three feet apart and on another on continuous wooden sleepers The difficulty with flat iron rails was referred to in a letter by Mr A C Jones of Philadelphia written on April 15 1834 to the editor of the *Journal of the Franklin Institute* In this letter Mr Jones said that on the Little Schuylkill Railroad there were two locomotives plying, and during the course of the last season they ran off the track fourteen times Wooden roads he considered the only proper kind for locomotives but the trouble arose from the flat iron rails 2 in wide and ⅝ in thick being joined improperly Such plate rails were, however soon afterwards abandoned for the inverted T shaped rail originally introduced by Robert *Livingstone Stevens in 1830*

Audubon s Birds of America

The year 1834 saw John James Audubon the American ornithologist continue his visits to England to exhibit his bird paintings in order to raise subscriptions for the publication of his work on The Birds of America Early in March 1834 he left Charleston and passed north to Washington Baltimore and New York In a letter of April 6 to Miss Maria Martin Audubon wrote that he had collected £600 and had sent £500 to Mr Victor in bills of exchange to await them at London Audubon his wife and son John finally sailed from New York on April 16 1834 in the packet *North America* for Liverpool In a letter written the day before he sailed to Edward Harris acknowledging receipt of 400 dollars in advance for a copy of his book he wrote My drawings shipped from Charleston are safely in the hands of Victor at London I have been able to forward to him 650£ and I have 30 sovereigns to defray expenses from Liverpool to the Great Metropolis In 1824 poor J had dreams but how far was I then from believing that I should ever have succeeded as I have who will believe my story ? Only one or two besides yourself have an idea of what I have undergone but if God grants me life I shall publish that story and send you sheets thereof as they are struck by the printer

Audubon brought to England all the collections he had accumulated in three years travel in the United States and British possessions and the passage to Liverpool took him nineteen days On arriving at Liverpool Audubon renewed his friendship with the local naturalists though Roscoe founder of the Liverpool Botanic Gardens had died since his previous visit His stay was brief and he continued on to London arriving there on May 12

Marine Steam Engine Improvements

With very few exceptions all early steam vessels had engines fitted with jet condensers and used sea water in their boilers The principal pioneer of the marine surface condenser as used to day was Samuel Hall who was born at Basford Nottingham in 1781 and died in 1863 at Bow in East London Hall had been successful with patents for gassing lace and net and was fifty years of age when he turned his attention to the marine steam engine He took out several patents one of his most important being No 6556 of Feb 13 1834 for a combination of a circulating pump an air pump a tubular surface condenser and an evaporator Shortly after this on April 19 1834 the *Mechanics Magazine* noted that the well tried favourite of the public the *Prince Llewelyn* now plying twice a week betwixt the Menai Straits and Liverpool is the first packet that has been fitted out on Mr Samuel Hall s principle for the improvement of steam engines consisting of a superior method of condensing the steam and using fresh instead of salt water thereby creating a great saving in the boilers and at the same time consuming one third less of fuel In spite of the many advantages of Hall s improvements surface condensers were not used on a large scale until forty years later

Professional Organisations and Modern Industry

IN a survey of modern industry from any point of view four tendencies are easily discerned as characteristic of conditions to day in contrast with those of a couple of decades ago The first of these tendencies is the growing scale of industrial enterprise and particularly the growth in size of the industrial unit It is true that the number of small firms in British industry remains surprisingly large but the growth in size of the leading firms is unmistakable particularly in chemical industry Although chemists are employed in such an immense range of industries those employed by really large firms represent a very considerable proportion of the numbers of the profession who are engaged in industry

The second tendency is the growing complexity of modern industry Not only is competition, whether in national or international markets generally more severe but also the complexity of manufacturing problems has increased The range of products produced by an individual firm will frequently be found to have multiplied several fold and the reactions involved in the displacement of old by new products frequently present those responsible for the direction of industry with some of their most difficult problems

Both the growing scale of modern industry and the increasing complexity of its operations have made the wise direction of industrial enterprise one of the outstanding needs of our time The importance of technical factors in administration has increased at the very time when the consequences of a mistake in administration have also increased their power Society can no longer afford to allow large scale enterprise to be directed by the *entrepreneur* and is already beginning to realise that our industrial prosperity largely depends on the direction of industry being based so far as possible on definitely ascertained facts and not on experience

Closer consideration of this question of scientific management brings to light the third factor which characterises industry to day The increase in the average size of the industrial unit has been accompanied by a growth in the importance of the duties which fall to those occupying the higher salaried positions There is already a pronounced tendency for salaried business administrators to be professional men and for those at the head of large concerns and bearing the responsibility of ultimate decisions to be drawn either from professional men or from those who, like the accountants, are tending to come under professional influence There is less and less place in positions which carry powers of ultimate direction for men lacking professional technique and that kind of training and experience out of which a technique is now being evolved It is probably true, as Prof Carr Saunders has suggested, that under a system of large scale commercial and industrial organisation, all those who occupy the important positions will come within professional associations or at least under professional influences It is certain that the incompatibility of profit making with professionalism is no longer an obstacle to the spread of professionalism through industry

Closely related to this is a fourth factor—the extent to which the spirit of service is taking hold of industry This may be seen on one hand in the way in which co operation between the manu facturer of a product and the users is facilitating the development of products giving better service It is equally seen in the growing degree to which men of high personal character and cultural vision are finding in management a sphere of social service One of the fundamental characteristics of the professional outlook is its emphasis on service , and to the extent to which the control of industry passes into professional hands we may expect to see the spirit of service increasingly influence its conduct Apart from this, there is a marked and growing tendency in public opinion to judge large scale industry by the fidelity with which it serves the public weal rather than by its success in amassing huge profits

These four tendencies are of fundamental importance in considering the position of pro fessional organisations in relation to industry When in the early years of the British Association of Chemists there were formed within that organ isation groups of chemists engaged in specific industries, such as the Guild of Textile Chemists, or the Guild of Dyestuffs Chemists, it was thought that one of their functions might have been to assist in the growth of industrial co operation, either in such matters as industrial safety or in representations to the Government on matters of public policy During the last ten years, apart from the growth in size of firms in chemical industry, such associations as the Association of British Chemical Manufacturers or the Federation of British Industries have grown up, which are giving regular attention to such matters and through which corporate representations to Government are naturally and readily made by accredited representatives of industry Such associations obviously already have within them the germ of the 'councils of industry' advocated by Mr Harold Macmillan and others as a basis for an industrial parliament

The function of professional organisation in industry from this point of view must obviously be somewhat narrower To admit this is not to deny the value and imperative necessity of defence associations To be effective, representations to the State from a body of industrial professional workers must obviously be confined to matters of definite professional importance, such as conditions of employment, training and so on In this field, however, very useful work remains to be done The increase in the size of the industrial unit, so far as the chemist is concerned, has probably tended to increase his security, conditions of service and remuneration The experience of the British Association of Chemists, however, indicates that there is still a great deal of work to be done in protecting the interests of chemists employed in less organised industries and by smaller firms Probably the risk of undercutting in the profession of chemistry is less to-day than in the past, but it is to the credit of the profession that such a relatively large proportion of those holding senior or secure positions in industrial work are members of their professional defence association

Education is a matter in which professional associations have always been more or less interested Under modern industrial conditions their active concern is more than ever required The task of planning educational policy, not merely qualitatively but also quantitatively in relation to the recruitment capacity of industry, can scarcely be solved without co operation from the professional organisations, worthy of the best efforts of even the Institute of Chemistry's fine record

One effect of the increase in size of the industrial unit has been to diminish the mobility of the professional workers in industry This has some bearing on both professional and industrial efficiency It increases the risk of grooviness and militates against the influx of personnel, less familiar indeed with the detail or technique of an industry, but more receptive of new ideas and better able to exercise a detached critical view This is a matter of sufficient importance to research to merit the attention of professional associations.

It should not be impossible to suggest some system of exchange or interchange which would be of immense value to all concerned

The question of industrial safety itself is by no means outside the legitimate sphere of work of professional associations In the main it is true their most effective work will be done through the maintenance of a high spirit of public service among their members, but recent events suggest that on occasion something more may be required It is at least open to discussion whether when a firm, for good or bad reasons, declines to accept the protection of the patent law and operates a secret process, the liability to disclose the full details in the event of any accident or loss of health or life should not be one of the risks incurred It is inconsistent with the ideal of a profession to permit the concealment of information which may have a vital bearing in health and safety in other quarters of industry

The second and third characteristics of modern industry, its growing complexity and the growth in importance of the duties which fall to the lot of the professional worker occupying the higher positions in industry, more than balance, however, any loss of influence of his professional organisations Professional influence in industry is now, and to an increasing extent will be, exerted largely through the individual members of the profession occupying important posts in which professional ideals influence industrial decisions and policy This factor alone makes it essential that professional organisations themselves should corporately not only be alive to these possibilities but also animated by the very highest professional traditions Professional workers, individually or collectively, are interested in doing a job well, in industrial and professional efficiency, only professional association can secure them the independence in which the finest professional ideals flourish and are practised

There is probably nothing more needed to heal the ills of our industrial and social world to-day, whether regarded from a national or from an international point of view, than the spread of just that spirit of service which is the quintessence of the professional spirit The extent to which that spirit has already found a foothold in industry, and to which it is already expected of industry, should embolden all scientific workers to address themselves individually and collectively to the task of relating knowledge and power in the service of society and industry

About Birds

(1) *Northward Ho!—for Birds from Wild Moorlands of England to Moorlands and Marshes of Scotland and Shetland, Öland and Lapland* By Ralph Chislett Pp xvi+188+44 plates (London *Country Life*, Ltd, 1933) 15*s* net

(6) *The Nidification of Birds of the Indian Empire* By E C Stuart Baker Vol 2 *Turdidæ—Sturnidæ* Pp vii+564+6 plates (London Taylor and Francis, 1933) 30*s*

THERE is no branch of zoological science which offers so wide an appeal to human interests and so many avenues for the acquisition of new knowledge as the study of birds, and so it is with books about birds At one end of the scale are the systematic, cataloguing, dry tomes devised for the use of the specialist and no other—matter without much life, at the opposite end are those volumes which place all their eggs in one basket, the photographs meant to catch the eye and the pence of a Nature loving public—life without much matter

It is very noticeable that during recent years a change has been coming over both extremes Perhaps the stress of competition of numberless bird books, perhaps the demands of the reading public for more intelligent guidance, perhaps the re-awakening of a new interest in natural history, have one or all helped to raise the standard of the modern bird book In any event, it is seldom nowadays that, on one hand, the systematic treatise or regional fauna does not allot a large proportion of its space to the habits of birds, and, on the other, that the one-time picture book does not contain observations upon the objects of its photographs which are of real scientific value So the two extremes tend to approach each other on the common ground of natural history, and the science of bird lore gains by the change in mood

From a long series of books about birds received at the office of NATURE, we have made a selection of examples illustrating the most outstanding types of bird books, and each is excellent of its kind

(1) Northward Ho!" belongs to the new type of picture book, that is to say its photographs are of first quality, and its text is well written, readable and observant Its specialty is that it avoids the commoner species and in Scotland makes for such as the crested tit, greenshank, red and black throated divers, great and arctic skuas, whimbrel, and in Scandinavia for such as the turnstone, fieldfare, redwing, blue throat, wood sandpiper, jack snipe—most of them familiar enough to us in their winter garb, but to most of us unknown in their breeding haunts

(2) Ian M Thomson has found the greater part of his quarry in Shetland and on the Norfolk Broads The plates, unusual in form since the picture fills the page to the edge, are the most striking bird photographs the reviewer has seen The text is relatively short, but it is good, some interesting observations, picked at random from many, are the carrying of chicks in its beak by a water rail, the contrast between the defence of a young bittern which strikes with its bill, and of a young Montagu's harrier which strikes with its claws the action of the latter bird and of a water rail, both of which played with extraneous objects while brooding In the description of Plate 15, 'beak should be back', as in the text

(3) Mr Edmund Selous, whose death we regret to see announced, has produced quite a different type of bird book a serious effort to elucidate the evolution of habit by the interpretation of laborious observations made in the field Whatever habit he touches upon, Mr Selous deals with it suggestively the replacement of the fight in earnest by make-believe 'scrapping', the origin of simple nests like the lapwing's through movements associated with sex impulses, and so to more complicated nests, the beginning of courtship displays in sex posturing, the swallowing of the fæces of the young in the nest, as a possible addition to nutriment, the regular and extensive storing of acorns by Californian woodpeckers as a product of the simple habit of placing spruce cones in a bark crevice for convenience of pecking The author considers that the territorial proprietorship of birds is not 'consciously real", but he is in error in assuming that "territory" begins with the nest, and may not be associated with feeding, for American observations suggest the presence of winter feeding territories in some species Too much space is wasted on ill judged attacks against other scientific workers, and the pleasure of reading is destroyed by the cumbersome and involved style of expression

(4) This systematic account of the tits of Europe describes 15 species and 80 different races, but it is more than a descriptive catalogue, for it tells much about distribution and about habits, especially of nesting Where the opportunity was so good we should have liked to have seen more attempt made at mapping the ranges and analysing the relationships between the numerous geographical races

(5) For nearly a century and a half, the brilliantly coloured weaver finches of Australia have been kept in captivity, and many species have become quite domesticated The bird lover, whether he loves birds in cages, or prefers simply knowledge about birds, will find this a compendium of almost everything that is known about the natural habits and cage breeding of, as the coloured plates show, perhaps the most variously beautiful of cage birds

(6) Mr Stuart Baker continues his valuable accounts of Indian birds in a second volume upon nesting, practically a supplement to the Fauna of India series The nidification of 403 species and races belonging to some of the most familiar families is described Of 62 forms nothing of the nesting habits has been recorded, and often the descriptions are simply of the completed nest and its clutch of eggs, so that much has still to be learned about nest building, incubation, feeding and growth of the young, and so on If this work encourages observation of nesting habits at the expense of egg collecting, it will add to its great value to science In one of the most interesting nests in the world, and one of the most common in India, that of the tailor bird, the author states that the way in which the bird knots the thread with which it sews together the edges of a leaf or leaves, is unknown, and what possibilities of observational results are suggested by the record of peculiar and identical clutches of the Burmese race, obtained from the same creeper upon the porch of a cottage at an interval of eighteen years! Does it mean long life, or detailed hereditary transmission of egg characters? J R

Egyptian Astronomy

L'Astronomie égyptienne depuis les temps les plus reculés jusqu'à la fin de l'époque Alexandrine. Par E.-M. Antoniadi. Pp. xi+157+7 plates. (Paris: Gauthier-Villars et Cie, 1934.) 40 francs.

THE author of this work explains in his preface that, in view of the non-existence up to the present of any book treating of the different branches of the ancient Egyptian astronomy in detail, his object is to make good the deficiency. A special feature is an attempt to give the whole of the evidence on the subject which is to be found in Greek writers; to this end M. Antoniadi has copied and translated all the most important passages from those authors that he has been able to find in the Bibliothèque Nationale at Paris. Accordingly, we are given multitudes of passages translated from Herodotus, Plato, Aristotle, Ptolemy, Strabo, Diodorus Siculus, Lucian, Dion Cassius, Diogenes Laërtius, Hippolytus, Clement of Alexandria, Eusebius, the Emperor Julian, Porphyry, Simplicius, Proclus, Horapollon, Hermes Trismegistus, Stobaeus, to say nothing of Latin authors, Cicero, Pliny, Seneca, Macrobius and Censorinus.

There are seven chapters. The first consists of generalities'—the beginnings of the ancient Egyptian astronomy, presumed to have come originally from Ethiopia, the Egyptian priest-astronomers, the temples as observatories, with a digression on Egyptian mathematics (arithmetic, algebra and geometry), after which come some references to astrology and an account of various astronomical appliances known to have been in use in Egypt (the gnomon, sundials, waterclocks, graduated circles, meridian instruments, and so on). The second chapter begins with the relations which the Greek philosophers who visited Egypt (Solon, Thales, Pythagoras, Œnopides, Democritus, Plato and Eudoxus) had with the Egyptian priests and what they may be presumed to have learnt from them. After this a short sketch is given of the great discoveries in astronomy due to the Greeks themselves, including the deposition by the Pythagoreans of the earth from its assumed place in the centre of the universe, and the anticipation of the Copernican hypothesis, partly by Heraclides of Pontus so far as the axial rotation of the earth and the revolution of the planets Mercury and Venus about the sun are concerned, and completely by Aristarchus of Samos.

The statement on pages 28 and 29 of the debt of the Greeks to the Egyptians will no doubt be found by most experts to be decidedly exaggerated. It is well known how ready the doxographers and other Greek writers were to attribute to the Egyptians the invention of every sort of thing; and M. Antoniadi seems to take their testimony at its face value, sometimes even going further, as when, from a passage of Seneca to the effect that "The courses of the five planets were not determined. Eudoxus was the first to bring this theory from Egypt to Greece", he concludes that the reference is to the theory of epicycles, and that the Greeks owed this to Egypt. Those conversant with the limitations of Egyptian geometry as it appears in the surviving documents will not be likely to credit the Egyptians' capacity to deal with a theory like that of epicycles; rather it required for its discovery a genius such as that of Apollonius of Perga, the 'great geometer'; moreover, Eudoxus is not connected by any authority with the hypothesis of epicycles.

The same chapter has, however, an interesting suggestion about the Pythagoreans' non-geocentric system in which the earth, with the sun, the moon, and the five planets, revolved in circles round the "central fire", namely, that the 'central fire" was really the sun all the time, but that Philolaus felt constrained to resort to camouflage for fear of a fate such as very nearly overtook Anaxagoras for declaring that the sun was a red hot stone. M. Antoniadi (who has also developed his suggestion in some separate papers) relies, first, on a comparison of the descriptions by Simplicius, Stobaeus and others of the "central fire" of the Pythagoreans as containing the creative and governing principle in the universe, with passages of Plato, Aristotle, Cleomedes and others speaking of the sun in very similar terms; secondly, on the odd tradition that Philolaus said that there were *two* suns, the sun which we see being a sort of mirror receiving and concentrating the reflection of the "fire in the universe" and transmitting it to us, this statement again being held to be part of Philolaus' deliberate camouflage disguising his real meaning.

The end of the chapter is on Copernicus, and maintains that Copernicus owed far more to the Greeks than he would admit; the author quotes a score of passages from Copernicus, whom he likes to call "the Canon of Frauenburg", side by side with as many closely similar passages from Greek authors (Plato, Aristotle, Ptolemy, Cleomedes, Plutarch and Aëtius), suggesting that

"Le chanoine de Frauenburg oubliait bien souvent la source de son inspiration"

To return to Egyptian astronomy Chap iii is on the Egyptians' astronomical divinities and their ideas on the universe, Chap iv on the Egyptian constellations, their names and their situations on the circular star map from the Temple at Denderah now in the Louvre (as early as the second millennium B C the Egyptians knew at least forty three constellations) Chap v is on the sun, moon and planets (the Egyptians had of course distinguished the zodiac as the circle in which they move), with their names and respective representations, chap vi is on the earth and the Egyptian calendar (the Egyptians had arrived at a year of 365¼ days) The final chapter (chap vii) is on the astronomy of the great pyramids It consists of forty pages and gives a mass of details about them, their dimensions, their exact orientation and their supposed astronomical significance, with special emphasis on the sloping entrance passages which, being almost exactly in the plane of the meridian, were adapted to serve as "colossal meridian instruments, by far the largest ever constructed', in the observation of the circumpolar stars

The attraction of the book is much enhanced by the highly interesting plates and illustrations

T L H

A Panorama of Physics

The Development of Physical Thought a Survey Course of Modern Physics By Prof Leonard B Loeb and Prof Arthur S Adams Pp xv+648 (New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd, 1933) 23*s* net

WITH the increasing complexity and development of science, the tendency becomes more evident for textbooks to appear, not only on the different sub-divisions of any particular branch of science, but also on each of the various aspects and further sub-divisions of these branches The number of works essaying to give a historical survey of physics as a whole and correlating the various sections, with due consideration of the philosophical basis, being distinctly limited, one approaches the present volume with more than ordinary interest, even though it was intended to meet the needs of a certain type of college course, rather than those of the general reader

The authors have attempted to compile a general fifteen weeks' course open to all students of arts and science irrespective of previous exposure to 'high school' physics, and comprehensible to a majority having only an elementary knowledge of mathematics The authors further state that it was therefore decided to "organise the subject in terms of the development of human ideas and concepts of the physical world", to give the manner of their evolution into modern physical science, and "at no place to introduce equations, laws, or phenomena without establishing their origin and their relation to other portions of the subject", the latter being "in every case shown to be the result of a controlled experiment or observation, or else a relation derived from such facts" It is not to be wondered at that the task is admitted to have proved exceedingly difficult, and one marvels at the range of matter covered in a text which copes with such extremes as giving (in a footnote) an explanation of the sine of an angle and, later, the Lorentz transformation formulæ, the Planck equation and the Einstein specific heat expression, or expounding why the formula of water is H_2O and not HO and giving, seven pages farther on, the Wöhler synthesis of urea, and in due course a detailed table of the extra nuclear electronic configurations

Every imaginable topic seems to be included from the phlogiston theory to the Heisenberg uncertainty principle The theme of historical development is adhered to throughout, while in the whole treatment mathematics is subsidiary and assumes little more than a knowledge of elementary algebra, although in one or two places the language of the calculus is introduced without any adequate explanation

The book opens with a historical survey of fifty pages dealing with science and philosophy under the Greeks and Romans, as well as much general history covering scholasticism, feudalism and the Church The foundation and work of the Royal Society receive due consideration

The first of the five main divisions of the book covers mechanics from the inclined plane to the theory of relativity, in the second part, heat and structure of matter, we go from thermometers and elementary heat to the laws of thermodynamics, entropy (which is vaguely discussed, but not defined), following which the rise of chemistry, gases, mean free path, Brownian movement, Van der Waals' equation, atomic field forces and quantum theory pass kaleidoscopically before the reader The next section, devoted to electricity and magnetism, covers Maxwell's laws and the magneton, and is succeeded by light, where, unlike in the case of the other subjects, elementary matter is omitted, but which in twenty-seven pages manages to range from Newton's spectrum, over the wave and corpuscular theories, to the ether, the interferometer and the Michelson-Morley experiment. The final section, on the electrical structure of matter, and the new physics, is perhaps the most ambitious in its comprehensiveness, for here the ramifications of the quantum theory are enlarged upon, with the addition, among others, of paragraphs on the Zeeman and Compton effects, artificial transmutation, neutrons, cosmic rays and wave mechanics and its developments. A complete enumeration would, in fact, cover almost every field of modern physical research. A detailed bibliography of works for subsequent reading is appended. Apart from some Wilson cloud track photographs, and in particular, excellent ones in connexion with the most recent work on disintegration and the neutron, the book is illustrated only by a sparse selection of conventional line diagrams.

It is undeniable that the authors have accomplished a remarkable undertaking. The text is thoroughly up to date, and readable in style, while the absence of heavy mathematics must commend the book to a wide circle. On the other hand, of course, the immense range attempted has necessarily restricted to a minimum the information on any given topic. The difficulty is to estimate the probable effect of a study of a work of this class on any particular type of reader. The person who wanted to know "a little about everything" would undoubtedly feel he was ideally served; the lay reader would probably be unequal to the task of orientating his mind to get a true perspective of modern science, although he could not fail to gain much useful information; the general scientific man might feel that he had been provided with a readily digestible refresher course, and the expert that the complex picture of contemporary science had been considerably clarified.

N. M. BLIGH.

Short Reviews

Handbuch der Biochemie des Menschen und der Tiere. Herausgegeben von Prof. Dr. Carl Oppenheimer. Zweite Auflage. Ergänzungswerk. Band 1, Halbband 1. Pp. xv+598. Band 1, Halbband 2. Pp. xv+601–1154. (Jena: Gustav Fischer, 1933.) 74 gold marks.

THESE volumes are of the kind that fill the user with awe-inspired gratitude and the reviewer with awe-inspired terror. That is to say, they are compilations exemplifying to the highest degree German thoroughness in surveying and abstracting literature.

The two volumes before us actually constitute two half volumes of a single volume; they run to 1154 pages altogether, of which the last 24 are devoted to a subject index. The double volume constitutes a supplementary volume to volumes 1, 2 and 3 of the second edition of the "Handbuch", published some eight to ten years ago. Presumably volumes 4–10 of the "Handbuch" will require at least another two supplementary double volumes also.

Even those who have some conception of the rapid strides made in biochemistry during the last decade must be astonished at the extent of the work done, as indicated by the scope of these supplementary volumes. A list of those who have collaborated in their production with Dr. Carl Oppenheimer, the editor, is sufficient guarantee of their adequacy in carrying out his ambitious purpose, which is to bring the original "Handbuch" so far as possible up to date at the end of 1932. The names of Profs. Abderhalden, Baudisch, Butenandt, Hoppe-Seyler, Krebs, Pringsheim, to take a half-dozen at random, make further recommendation supererogatory. It should be sufficient to say that the three original volumes of the work, to which these two volumes are supplementary, cover the building materials of animal tissues, the biochemistry of the cell, and the field of general immunological chemistry. This supplementary volume is indispensable to those who possess the main work, and will also be of great value to those who are not so lucky.

A. L. B.

The Romance of Research. By L. V. Redman and A. V. H. Mory. (A Century of Progress Series.) Pp. x+149. (Baltimore, Md.: The Williams and Wilkins Co.; London: Baillière, Tindall and Cox, 1933.) 5*s*.

THIS book depicts, in concise yet lucid and felicitous terms, "the viewpoint of research and something of its methods, its developments, and its achievements". The man of science and the technologist, no less than the thinking layman, will find much that will interest them; but to no one will it make a stronger appeal than the research student, especially the young investigator who is on the threshold of an industrial career.

Notwithstanding the small compass of the book, the authors have succeeded in presenting a delightful sketch of the progress of research in many branches of biological and physical science, in showing how the community has benefited from the patient researches of those who sought no personal reward and in illustrating and explaining the major problems which must be solved before a laboratory discovery can be successfully translated to a large scale process As director and associate director of research to the Bakelite Corporation the authors have had ample opportunity of realising the advantages which result from sustained investigations so they do not hesitate to preach research to those who are more interested in its exploitation than in its promotion It is a stimulating book and deserves to be widely read W H B

Modern Coffee Planting By E G Windle Pp xi+232 (London John Bale Sons and Danielsson Ltd n d) 10*s* 6*d* net

The author of this book is a planter of more than fifty years experience in the coffee districts of South India His experience thus dates from the days when coffee was grown without shade before the disease *Hemileia vastatrix* levied such a heavy toll on this industry in the East The book is addressed to planters and is based on personal experience and observation It is seldom that one has the privilege of reading a book on a particular crop written by one who has made it his life study and has at the same time earned his livelihood from it Though written primarily for the coffee districts of South India where coffee has been grown since the seventeenth century the book should prove of great value to other coffee growing countries especially those where the industry is comparatively young Local conditions vary from one country to another but knowledge of a particular crop which has been acquired by experience will always prove useful elsewhere to anyone who makes an intelligent study of it

The dedication of this book to His Highness the Maharaja of Mysore in grateful acknowledgment of the benefit to the Coffee Industry resulting from the establishment of the Coffee Experiment Station at Balehonnur is welcome evidence that the author has put into practice the results of research to his own benefit

Constitution and Health By Prof Raymond Pearl (Psyche Miniatures General Series No 60) Pp 97+5 plates (London Kegan Paul and Co Ltd 1933) 2*s* 6*d* net

This little book is an expansion of a lecture given at the Army Medical Centre Washington It discusses the problems of the human constitution with the author s usual lucidity of style taking the view that the constitution of an individual is determined not only by his genetic inheritance but also by the exigencies of his lifetime such as the infections to which his body may have reacted producing immunity The constitution of an individual is therefore subject to change throughout his history and statistical treatments are necessary to determine the inter-relationships involved in the series of complex variables anatomical physiological psychological and pathological which characterise a human being The asthenic and pycnic types are regarded as merely extremes in a continuous series Dysplastic or asymmetrical types also occur having for example legs of one somatological type and trunk of another Such may be regarded as a coarse form of mosaic inheritance All the general modern biological interpretations are touched upon

Islands of the West By Seton Gordon Pp xv+211+47 plates (London Toronto Melbourne and Sydney Cassell and Co Ltd 1933) 15*s* net

Descriptive books on Scotland even of the west of Scotland have appeared in unusual numbers during the last few years most pitching their appeal to the alien tourist The book before us is not a guide book to the western isles but a series of essays dealing with one and another aspect of the islands and their life human and animal from Skye and the St Kilda group to Ailsa Craig and wandering beyond these bounds to Scilly and Connemara Yet we doubt if any other book can convey so vividly to the mind of the reader the loneliness and pathos as well as the *camaraderie* of existence upon these outliers of civilisation The result is partly due to the fine word pictures of the islands and their people but also to the way in which myth and tradition have been interpolated to illustrate a mental outlook which belongs to the past and as one would expect there is much said about the wild life of the places the author has taken such pains to visit The book is illustrated by striking and beautiful photographs

Die Faden Elektrometer Von Theodor Wulf Pp 147 (Berlin und Bonn Ferd Dümmler 1933) 6 gold marks

It is useful to have such a complete account of the string electrometers Although the theory relates to electrometers in general the greater part of the book deals with string electrometers Their construction use and calibration are described in great detail The double string electrometer is treated first and the single-string second In the latter case is a first account of the attainment of enhanced sensitiveness by using such potentials and distances between plates that the string is approaching an unstable condition The measurement and effect of the capacity of the instrument are described at length

Cours de mécanique rationnelle (Cours de la Faculté des Sciences de Paris) Par Jean Chazy Tome 2 *Dynamique des systèmes matériels* Pp vi+460 (Paris Gauthier Villars et Cie 1933) 80 francs

This volume takes the reader through the mechanics of systems following the work of the earlier volume on the dynamics of point bodies The two volumes together form a course which will supply the university student s need up to the stage required for the degree in mathematics

The Giorgi (M K S. Ω) System of Units

SEVERAL years ago, Prof Giovanni Giorgi, professor of mathematical physics in the University of Palermo, proposed a new system of electrical units At a meeting of a section of the Advisory Committee on Nomenclature of the International Electrochemical Commission in October last, a resolution was passed inviting national committees to express their opinions on the extension of the series of practical units at present employed in electrotechnics in the direction of Prof Giorgi's system

In this system there are four fundamental units, namely, the metre, kilogram, second and ohm

Dealing first with mechanical units and their relation to the C G S system, the changes are simple We then have

Length	1 metre	= 10^2 C G S units
Mass	1 kilogram	= 10^3 ,, ,,
Time	1 second	= 1 ,,
Velocity	1 m per sec	= 10^2 ,,
Momentum	1 kgm at a vel of 1 m per sec	= 10^5 ,, ,,
Force	1 vis*	= 10^5 dynes
Energy	1 vis acting through 1 metre	= 10^7 C G S units = 1 Joule
Power	= 10^7 C G S	= 1 watt

When, however, we pass to electromagnetic questions, we are met with a difficulty Maxwell attempted to express the measures of the various quantities occurring in terms of the three fundamental variables of mechanics—length, mass and time, and found that, without further assumptions, this was impossible

The fundamental electrical quantities are four in number, and other quantities occurring can be expressed in terms of these† We have the strength of an electric charge, ϵ, the strength of a magnetic pole, m, the permissivity of air, or a vacuum, K_0, the permeability of air, or a vacuum, μ_0 The measurements we make connecting these four quantities with our three mechanical units are three in number namely, the force between two charges, the force between two poles, the force between a current element and a pole, or alternatively, the force between a current circuit and a magnet Thus we have insufficient experimental results to express our four fundamental electrical quantities in terms of our mechanical units

We are left, as is well known, with the result that the dimensions of $\sqrt{\mu_0 K_0}$ are those of the reciprocal of a velocity, and we can proceed no further without some additional assumption We cannot say what are the dimensions of μ_0 and K_0 in terms of mass, length and time We know, of course, that the velocity is that of the propagation of electromagnetic waves, but that does not add to our knowledge of the dimensions of μ_0 and K_0 An additional fundamental unit is required

Maxwell's systems are based on one or other of two alternative assumptions one—the electrostatic system—that K_0 is unity and therefore $\mu_0 = 1/V^2$, where V is the velocity of wave propagation the other—the electromagnetic system—that μ_0 is unity and K_0 therefore equal to $1/V^2$ In the first, $K_0 = 1$ gives us the fourth fundamental quantity, while in the second $\mu_0 = 1$ takes its place as such

These are not, however, the only possible assumptions Any one of the quantities we wish to define might be assumed as a fundamental unit It might for example, be a quantity of electricity measured by its electrochemical effects, or in some other way independent of that already employed when measuring the force between two charges—this has been developed by Prof W Cramp in a letter to NATURE[1]—or a current of electricity measured in a similar manner This was Prof Giorgi s suggestion in some of his earlier papers

In his later papers, he adopts the resistance of a certain bar of metal, and thus we have his M K S R system Any suitable bar of metal might be taken for example, the resistance between the ends of the standard metre But it is universally agreed that any system of practical units must be the volt ampere ohm system, and this fixes the unit of resistance as 1 ohm Prof Giorgi therefore takes as his fourth fundamental unit a material bar having a resistance of 1 ohm, or more exactly 1 international ohm, and fixes on a column of mercury at a temperature of 0° C, 106 300 cm in length, having a mass of 14 4521 gm Thus except for the 4π question, we arrive at the M K S Ω system

The C G S system is based on Coulomb's law of force between two electric charges written in the form

$$\text{Force} = \epsilon\epsilon'/K_0 r^2$$

Prof Giorgi prefers to use Heaviside's form

$$\text{Force} = \epsilon\epsilon'/4\pi K_0 r^2$$

and thus eliminates the 4π in the expression for magnetomotive force

On the C G S system we have magnetomotive force $= 4\pi$ ampere turns and the unit of magnetomotive force is $1/4\pi$ ampere turn, whereas on the Heaviside system the unit is the ampere turn

The effect of this is to throw the 4π into the value of K_0 Thus we know that, in air, on the electrostatic system, when $r = 1$ cm $= 10^{-2}$ metre and $\epsilon = \epsilon' = 1$ C G S unit $= 10$ coulombs, then the force of repulsion is 1 dyne $= 10^{-5}$ vis

$$\text{Hence } 10^{-5} = \frac{1}{4\pi K_0} \times \frac{10^2}{10^{-4}}$$

$$\text{and } K_0 = \frac{1}{4\pi} \times 10^{11},$$

---

* Vis is the name given by Prof Giorgi in one of his papers to the unit of force

† We might take other four quantities as fundamental, but this would not affect the argument.

or as Prof Giorgi writes it

$$K_e - \frac{1}{4\pi} \times 10^{9} L,$$

where L stands for the unit of length, the metre

In the above, for the sake of simplicity, Coulomb's laws have been assumed as the basis of the theory on which the system rests This, however, is by no means necessary In a very interesting article in the "Enciclopedia Italiana—Elettricita, Theoria della", to which Prof Giorgi very kindly referred the present writer in reply to a request for information on some points of theory, he has in the most lucid manner "developed the three fundamental schemes, pre Maxwellian, Maxwellian and electronic Any of these can be taken as the starting point

As Prof Giorgi stated in a paper read before the Electrical Congress at St Louis in 1904, neither the C G S electrostatic nor the C G S electromagnetic system is touched Scientific workers will be free to use any one of these systems without modification, or substitute for them his absolute practical system

To sum up, quoting again from the same paper "In order to derive electric and magnetic units from mechanical units, a fourth fundamental unit is necessary In the C G S electrostatic and the C G S electromagnetic systems, the fourth unit assumed is respectively the electrostatic or the electromagnetic constant of free ether, but this has many disadvantages For the absolute practical system the fourth unit is the ohm " It would be more accurate to say the international ohm, defined as the resistance of a certain column of mercury '

It should be noted, of course that the two changes from the C G S system suggested by Prof Giorgi are quite independent

Heaviside's suggestion as to the 4π could be introduced without adopting Prof Giorgi's proposal to take the international ohm as the fourth independent unit

√ The Inheritance of Acquired Habits

By PROF E W MACBRIDE, F R S

FOR the last five years, experiments to test the heritability of acquired habit have been in progress in the Zoological Laboratory of the Imperial College of Science under my supervision and an account of the work may be of interest to readers of NATURE

The first part of the results of these experiments has been published by the Royal Society the second part is almost ready for publication Miss Sladden, who carried out the work began by rearing the young of *Salamandra maculosa* and the eggs of *Alytes obstetricans*, thus endeavouring to repeat Kammerer's work It became evident, however, that we did not possess the equipment necessary to provide the conditions which would induce these animals to breed We succeeded in confirming some of Kammerer's statements about the effect of the environment on the habits of one generation Thus it is quite possible to induce *Alytes* normally a land animal, to adopt an aquatic life, and in regard to *Salamandra* we were enabled to explain Herbst's failure to obtain Kammerer's results

There are two distinct races of *Salamandra maculosa*, an eastern and a western In the latter, which inhabits the Jura and the Vosges, the yellow pigment is arranged in two longitudinal bands on the back, over a general body colour of black Miss Sladden has reared animals of this race from birth to an age of three years in boxes painted inside with bright yellow and also in boxes painted deep black inside In neither case could we detect any alteration in the amount of yellow pigment as a result of the colour of the background In the eastern race, however, which formed the subject of Kammerer's researches, the yellow pigment is arranged as a series of spots over a black background, and by experiments conducted by Mr E Boulenger, then curator of reptiles in the Zoological Gardens, and by myself, during the years 1919–1924 we were able to show that animals of this race exposed for long periods to a black environment do show definite reduction of the yellow pigment But even if Miss Sladden had been successful in getting her animals to breed, the length of time involved would have been prohibitive, since the adult condition is only attained after four years' growth Therefore we sought for a convenient experimental animal in which the generations succeeded each other more rapidly

Some years ago (1912–1915), in conjunction with another pupil (Miss Jackson, afterwards Mrs Meinertzhagen), I conducted experiments on breeding the stick insect, *Carausius morosus*, and I found that this insect, whose normal food in England is privet, could be forced by starvation to feed upon ivy I therefore suggested to Miss Sladden that she should test the development of this ivy feeding habit This insect offers great advantages when used as an experimental animal It is parthenogenetic males only appear in small numbers every five or six generations and when they do appear they are at once recognisable by their smaller size and different coloration The parthenogenetic insect produces about 150 eggs a year which take about three months to develop there is no metamorphosis and as there are no wings the nymph is morphologically similar to the adult

The plan adopted was to isolate the just hatched young, keeping each one in a separate box These boxes were made of metal they were circular and had glass covers In each box was placed a small piece of ivy leaf At the end of two days about ten per cent of the insects had begun to eat ivy, the rest had not touched it. If we had reared from these insects alone we should have been accused of selection; but we adopted a different plan (suggested by my colleague, Mr. Hewer). The ninety per cent which refused ivy were given a bit of privet leaf to eat and so rescued from starvation. Then after one day the privet was removed and the insect was again provided with ivy. This second provision of ivy was called the 'second presentation'. If after two days more the insect still refused ivy, it was again given privet for a day. The majority of the insects accepted ivy at the second presentation; but some held out until the third, fourth, or even fifth, presentation, and one recalcitrant held out until the tenth presentation.

We started the experiments with 125 females. All the young which accepted ivy at the same presentation, to whatever mother they belonged, were classed together, and when they in turn became adult the eggs of each class were mixed together. From each mixture 100 eggs were selected in order to rear the next generation. In the second generation, in place of ten per cent no less than eighty per cent of the insects accepted ivy when first presented, that is, at the first presentation; in all, 800 insects were tested. In the third generation ninety-five per cent accepted ivy at the first opportunity and 2,000 insects were tested.

Thus with these insects, we reached exactly the same conclusions as those arrived at by Prof. McDougall with regard to induced habits in rats; namely, that when members of one generation are compelled to adopt a new habit, a residual effect of this habit is carried over to the next generation, so that the young insects adopt the new habit more quickly than did their parents. We claim, however, that the stick insect gives more conclusive results than the rat; because although we think that Prof. McDougall has overcome all his difficulties, yet there were very serious objections to be faced with rats, such as possible mass suggestion, parental training, etc., which are obviously inapplicable to insects.

What many people fail to realise, however, is that this transference of a residual effect of habit is the central principle of Lamarckism, clearly and unequivocally expressed by Lamarck himself. He said that "the environment produces no direct effect on the animal", but by making new needs (for example, the necessity of eating ivy or starving) it forces the animal to make new efforts to satisfy them, and 'if these needs *continue for a long time* then the animal's efforts become habits'; and habits by causing the use of some organs more and others less bring about the enlargement of the former and the diminution in size of the latter, and these changes are preserved by reproduction.

This article is written in the hope that other investigators will take up this question and repeat the experiments using other animals, especially other insects, as subjects; for only by such experiments can this fundamental principle be settled. Indeed, experiments with the larvæ of moths were begun some years ago by Dr. Thorpe, of Cambridge. The attractive feature about such experiments is that the percentage of mortality is very low, so that the agency of 'chance' or 'natural selection' is excluded. Prof. Woltereck, whose great book "Grundzuge einer allgemeinen Biologie" was reviewed in NATURE of December 17, 1932, removed Cladoceran Crustacea from northern lakes to Lake Nemi in Italy. When he examined the transported stock after twenty years he found them much altered in shape; when he again re-transferred some of this stock to the post-glacial lakes of their ancestry they reverted to their original shape—but only *gradually during the course of several generations*.

The Linnean Society recently had the privilege of hearing Prof. Woltereck deliver an address on the fauna of recent lakes in many lands. Summing up the evidence, Prof. Woltereck concludes that the time since the recession of the ice of the last phase of the glacial age, that is, about 10,000 years, has only sufficed for the production of new races; for the production of new species we must go back to pre-glacial times possibly 500,000 years ago. As I remarked in my comments on the lecture it would be hard lines on the experimenter if he had to live and experiment for 10,000 years before he could hope to produce a new heritable *structure*; but heritable changes of *habit* in small rapidly breeding animals may be observed after experiments *lasting from five to ten years*.

Students of mutation, that is, 'geneticists', will naturally inquire what is the relation between these changes of habit and mutations. That is a question for future study; here only certain tentative suggestions can be offered. From the study of the few cases in which mutations have been experimentally produced by such agencies as X-rays and heat, it may be concluded that they are due to some damage to the developmental machinery of the nucleus in the germ cells. They, and not the Lamarckian changes, are the results of the 'direct action of the environment'. So long as malign conditions surrounding early development persist, the mutations are faithfully inherited, but if the organism can be replaced in its natural environment, then in a limited number of generations they pass off and the original constitution reasserts itself. In 1790 Capt. Cook introduced the English domestic pig into New Zealand in order to induce the Maoris to abstain from cannibalism. The animals escaped into the woods, and by 1840 had increased to herds of at least 40,000 in number and had assumed all the characters of the ancestral wild boar, including the fierce tusks—although in New Zealand there were no enemies which required such weapons to drive them off. Mutations seemingly are more surface phenomena than racial habits; they are indeed what Johannsen, the inventor of the word 'gene', called them, "superficial disturbances of the chromosomes", but racial habits belong to the inmost core of the heritable constitution.

The British Postgraduate Medical School

LONDON has a supply of clinical material—that is, cases of sickness and disease—almost unique in amount and variety, which should be available for teaching and research. Some of this material is utilised by the medical schools in their attached hospitals for the training of their undergraduate students, whom they must in the main serve, and their facilities for the additional training of the postgraduate student are necessarily limited. In fact London has hitherto lacked an organisation for postgraduation study comparable to the continental centres such as Vienna. London's wealth of clinical material should be available for the provision of courses of advanced instruction for qualified doctors resident in Great Britain, in the Empire beyond the seas, and abroad, who wish to refresh or extend their knowledge, or to obtain the latest information on new developments in medicine, surgery and obstetrics.

Attempts have been made in the past to institute courses of postgraduation study. In the closing years of last century the Medical Graduates College and Polyclinic, organised in the main by Sir Jonathan Hutchinson, gave courses of systematic lectures in various branches of medicine in association with classes and clinics in certain special hospitals and medical schools but it could not provide that regular attendance at in- and out-patient departments which is one of the principal requirements of the general practitioner and of the specialised postgraduate student. Postgraduate courses of instruction have also been organised by some of London's hospitals which have no medical school attached for example the West London, Hammersmith, the Prince of Wales, Tottenham, and the Seamen's Hospital, Greenwich.

Another organisation which has done and is doing, much good work in the direction of postgraduation study, is the Fellowship of Medicine and Post-graduate Medical Association, with which the name of the late Sir William Osler should be remembered. But its scope is limited much in the same way as in the Polyclinic.

The serious consideration of the problem of a postgraduate medical college dates back to 1921, when Dr. Addison, then Minister of Health, at the suggestion of the University Grants Committee, formed a Committee under the chairmanship of the Earl of Athlone to consider, among other matters, the provision in London of a school with hospital attached to be devoted to postgraduate instruction in medicine, and of an institute for instruction in public health subjects. Largely by the aid of a very generous grant from the Rockefeller Foundation, the last-named institution was the first to be established and the buildings of the London School of Hygiene and Tropical Medicine were opened in July, 1929.

The other objective of the Athlone Committee still remained to be secured, but the post-War depression had already begun and the scheme remained in abeyance for a time. Then Mr. Neville Chamberlain set up another committee, the terms of reference of which were "to draw up a practicable scheme of postgraduate medical education centred in London". This Committee surveyed the situation, and came to the conclusion that it was impracticable to establish a new school with hospital attached, or to associate the new school with any existing teaching hospital. But fortunately, by the passing of the Local Government Act of March, 1929, between twenty and thirty municipal general hospitals, formerly under the Poor Law, came under the control of the London County Council, and a scheme of associating the proposed postgraduate medical school with one of these institutions was then explored. With the full co-operation of the London County Council, the unanimous conclusion was finally reached that the conversion of the hospital in Ducane Road, Hammersmith, was the best solution of the problem. Here there were 400 beds housed in a building no part of which was more than twenty-five years old, and which had been described as "exceptionally good and well designed for the purposes of a hospital dealing with the acutely sick".

In April, 1930, Mr. Greenwood, then Minister of Health, announced the Government's acceptance of the Committee's recommendations and its willingness to contribute a sum up to £250,000 for building and equipping the School, together with annual grants for maintenance through the University of London. Following the recommendations of another Committee over which Lord Chelmsford presided a Royal Charter was granted to the School on July 10, 1931. Unfortunately, shortly afterwards the financial crisis developed and jeopardised the whole scheme but after serious consideration the Government of the day decided that it was against the public interest to postpone the scheme indefinitely, and offered to make a grant not exceeding £100,000, and the L.C.C. agreed to expend a similar sum towards adaptation of the existing Hospital for the purposes of the School.

Financial reasons again delayed the commencement of building, but the foundation stone was laid by Mr. Neville Chamberlain in July last year, and substantial progress has since been made in the adaptation of the existing buildings and provision of the new ones required.

The L.C.C. is providing, on the hospital side, new blocks for midwifery cases, for out-patients, and for casualty departments, while the School buildings will consist mainly of laboratories, lecture theatres, and accommodation (non-residential) for the teachers and students. The Dean of the School, Dr. MacKeith, has recently issued a circular descriptive of the general plan of the buildings and of the accommodation provided.

The University of London has also recently recognised' the new institution as a school' of the University, and four chairs have now been advertised, in medicine, surgery, obstetrics and gynæcology, and pathology Presumably assistants will also be needed for each unit, and it may be anticipated that courses will also be delivered from time to time by eminent physicians, surgeons and others not permanently attached to the School In addition, the courses in present postgraduate centres will still be made use of so far as possible

Thus, after many vicissitudes, a postgraduate medical school worthy of the great Metropolis has come into being which it may be anticipated will in the future raise the standard of professional skill among the great body of medical practitioners, and will advance the progress of medical science by research carried out within its walls

Obituary

PROF CAMILLE MATIGNON

ARTHÈME CAMILLE MATIGNON, president of the French Chemical Society who died suddenly in Paris on March 18 was a leading figure in pure chemistry and a great exponent of chemical technology Matignon was born at Saint Maurice aux Riches Hommes Yonne on January 3 1867 and entered the Ecole Normale Paris in 1886 three years later he became assistant to Berthelot at the Collège de France and commenced a long series of original contributions to our knowledge of thermochemistry After spending five years at the University of Lille as lecturer and professor he was appointed as a temporary professor at the Collège de France in 1902, a supplementary professor in 1903 and, on the death of Berthelot, became professor of inorganic chemistry in 1908 holding this post until his death

Matignon early concerned himself with the great problem of the fixation of atmospheric nitrogen and the synthetic production of ammonia he studied the direct combination of many of the metals with nitrogen, showing that zinc dust always contains zinc nitride, and preparing the nitrides of a number of the rare earth metals Certain of the nitrides, such as those of silicon and aluminium, were probably formed during the cooling of the earth and, by the action of water vapour, gave ammonia, the first form in which nitrogen became available for assimilation by plant life Matignon maintained that the increased use of artificial nitrogenous fertilisers was essential to the development of French agriculture, he followed up the advocacy of this principle by working out methods for the economic production of phosphates and potassium salts for use as manures

With the aid of the calorimetric bomb, Matignon determined the heats of combustion of a long series of substances and, since many of these were closely related organic compounds, he was able to deduce a number of interesting generalities from the heats of formation His more extended studies of the part played by heat in chemical reactions led him to the statement of an empirical law of thermodynamics which Nernst termed the Le Chatelier Matignon rule' This states that for gaseous equilibria in which one gaseous and one or more solid phases are concerned (sublimation of solids, dissociation of calcium carbonate, etc), the relation $Q/T = 32$ holds approximately in all cases Q being the heat evolved at constant pressure and T the absolute temperature at which the gaseous pressure attains one atmosphere This empirical law is an extension to chemical dissociation of Trouton s law concerning heats of vaporisation The Le Chatelier Matignon rule can be stated in several ways and may be used to foretell whether certain reactions can take place and whether they are reversible Thus it was foreseen that hydrogen sulphide should react with potassium carbonate but not with sodium carbonate at the ordinary temperature, these deductions were verified by experiment Matignon's achievements in these and many other fields were recognised by his election to the Institut de France in 1926

Matignon was an eloquent speaker and wrote in a lucid convincing style He assumed the editorship of the *Journal* of the French Society of Industrial Chemistry at its inception in 1918, and the editorial which he wrote each month until the end of his life was read with interest by the whole chemical world, the last of these articles—on the fiftieth anniversary of the death of Dumas—appears in the March number of *Chimie et Industrie* which was published a few days ago Matignon s striking personality and his gay vivacious enthusiasm made him a notable figure He did much to promote the re establishment of those normal relations between scientific men throughout the world which had been so rudely shattered by the War, he had many friends far outside his own country who will remember him with respect and affection

W J POPE

MR E G B MEADE WALDO

IT is with great regret that we have to record the death of Mr Edmund Gustavus Bloomfield Meade Waldo, of Stonewall Park, Chiddingstone, Kent, who died on February 24, aged seventy-nine years Only son of Mr Edmund Waldo Meade Waldo, of Hever Castle and Stonewall Park, he was born at Holly Brook, Co Cork, on February 8, 1855, and educated at Eton and Magdalene College, Cambridge His room at Eton was a menagerie of wild animals, and rumour has it that, while at Eton, his overpowering ambition was to kill one of the red deer in Windsor forest, and that this ambition was fulfilled In 1880 he married Ada Coralie, a daughter of the late Lord Justice Baggallay and he and his wife went to live for some time at Rope Hill in the New Forest The New Forest as was only natural brought out all that passionate love of Nature and animal life which had already begun to show itself at Eton

Like his life long friend Herbert St Quintin of Scampston Hall Yorkshire who died a year ago Meade Waldo was a born naturalist and both were fortunate in having leisure to develop more and more their powers of observation in all branches of natural history It is said that they corresponded almost every day of their lives and needless to say the subject of this correspondence formed an almost daily diary of what they had observed in the field of Nature If the many facts comprised in these remarkable series of letters could be gathered up it is probably no exaggeration to say that they would vie with those contained in White s Natural History of Selbourne

Both these friends were ardent hawkers and in this fascinating pursuit such other well known hawkers and naturalists as Lord Lilford Aubyn Trevor Battye W R Ogilvie Grant the Hon Gerald Lascelles Col H Barclay and the Rev Gage Freeman and others were very closely associated Meade Waldo s diaries contain many records of famous hawks and their prowess in the chase

Meade Waldo s life represents a page in the history of ornithology which is not likely to be rewritten Another of his intimate friends was the late Henry Elwes a man passionately fond of God s open spaces in many countries a naturalist in every sense of the word the author of one of the finest books on trees ever written Lord Grey of Fallodon was another friend after his own heart and Herbert St Quintin Meade Waldo and Grey forgathered every year at Fallodon All three have died in the last year and to those in sympathy with the point of view they represented their passing will inevitably represent a lost link with the ornithology of the past

But Meade Waldo s activities in the realms of Nature were not confined to his own broad acres or those of his friends He studied birds in Spain as also in Morocco where during a long residence he explored the Atlas Mountains in days when travel in that country was not the easy matter it is now He was also intimately acquainted with the birds of the Canary Islands and was one of the late Lord Crawford s guests on his voyage to Madagascar and the Comoro Group in his famous yacht the *Valhalla*

Meade Waldo was also an ardent supporter of the various societies for the protection of bird life the fauna of the Empire and the establishment of nature reserves while he took the deepest interest in the welfare of the Zoological Society of London of which he was a vice president and a member of the Council He was indefatigable in his attendance at the many meetings which such work involved

MR JOHN POWER

BY the death on January 27 at Rosebank near Cape Town of Mr John Power one of the few remaining direct links with the Royal Observatory Greenwich under the administration of Sir George Airy has been broken

John Power was born in Waterford Ireland on July 14 1860 He entered the Greenwich Observatory in 1875 six years before the retirement of Airy In 1891 he left to take up the appointment of secretary and librarian to the Cape Observatory under Sir David Gill In 1895 he was appointed a junior assistant being succeeded as secretary after a short interval by the late Dr R T A Innes who afterwards became the first Union Astronomer In 1905 Power was promoted to the rank of assistant From 1897 until his retirement in 1920 he was in charge of the miscellaneous computing department In that capacity he was responsible for the preparation and proof reading of the following catalogues (the dates of publication are in brackets) —Cape General Catalogue for 1890 (1898) the Cape General Catalogue for 1865 (1899) the Cape Astrographic Standard Star Catalogue (1906) the Cape Catalogues of Special Stars for 1900 (1906) the Cape Catalogue (Boss s Stars South of 36) (1907) the First Cape Fundamental Catalogue for 1900 (1915) the Second Cape Fundamental Catalogue for 1900 (1920) and the Cape Zone Catalogue of 20 843 stars for 1900 (1923) He showed remarkable industry and devotion in this work spared no efforts to ensure accuracy in all details and was very skilled in marshalling large masses of numerical data He rendered also very valuable services in connexion with the revision and control of the co ordinates of the plates for the Cape zones of the Carte du Ciel work and in their preparation for press For many years he was a regular and active observer with the transit circle

Power was much interested in local and municipal affairs He was largely responsible for the inception of a public library in Observatory (the suburb adjacent to and named after the Cape Observatory) of which he was chairman for many years preceding his death He was also for many years a member of the Cape School Board of which he became successively vice chairman and chairman After his retirement he devoted a great deal of his time to the work of this body on which he will be greatly missed Financial approval for carrying out the programme of the Board was often difficult to obtain but Power s Irish extraction showed itself in his love of a fight and he was at his best in defending his policy and attacking his opponents The cause of elementary education at the Cape owes a great deal to his efforts

Mr Power was a widower and his only son, who had had a brilliant career at Oxford as a Rhodes scholar was killed in action in East Africa

Prof J R Ainsworth Davis

PROF AINSWORTH DAVIS was born at Bristol in 1861 the son of the Rev James Davis He studied under Profs Huxley and Judd at the Royal School of Mines London and afterwards at Trinity College Cambridge where he gained a first in both parts of the Natural Science Tripos Shortly afterwards appointed lecturer at the University College of Wales Aberystwyth he threw himself into the work of that institution and was elected professor of zoology and geology He was a teacher of marked power and strong personality with an unusual gift for epigrammatic statement and he sought to understand and help his students outside as well as inside the class room His home was always open to students and colleagues and his versatility showed itself in amateur acting verse writing organising and commanding the college O T C campaigning for the hall of residence for women students—one of the earliest of these institutions as well as in scientific writing In the latter field he wrote papers some in collaboration with his students on molluscan morphology but his chief interest was in teaching and his textbook of biology his Natural History of Animals and other works have been widely used

In 1908 Ainsworth Davis became principal of the Royal Agricultural College Cirencester and from 1914 on he served as army instructor with the rank of major acting at one time as chairman of the Central Civilian Advisory Board at G H Q After demobilisation he lectured in biology at Middlesex Hospital Medical School and then gave his services as writer and lecturer to the Empire Marketing Board

His was a life of varied activity the outcome of a keen mind deeply interested in the life of his time He is survived by his wife daughter of the late Mr James Coutts of Edinburgh and by his son Dr J C Ainsworth Davis who has been a distinguished athlete

---

WE regret to announce the following deaths

Herr Oskar von Miller founder and until 1933 president of the Deutsches Museum at Munich and formerly a chairman of the World Power Conference aged seventy eight years

Prof Augustus Trowbridge professor of physics and since 1928 dean of the Graduate School of Princeton University an authority on explosive mixtures on March 14 aged sixty four years

Prof F P Venable emeritus professor of chemistry in the University of North Carolina and president of the University in 1900–14 on March 18 aged seventy eight years

News and Views

The Hon John Collier

THE death of the Hon John Collier on April 11 at the great age of eighty four years recalls his signal services to men of science in the art of portraiture The National Portrait Gallery possesses the popular and appealing canvas of Darwin standing clad in a cloak holding his hat in the left hand and looking straight towards the spectator Here too may be seen Collier s representations of Huxley Sir Michael Foster Sir William Huggins and W K Clifford mathematician physicist and philosopher The Royal Society is especially fortunate in examples of Collier s faithful portrayal of a select circle of men of science In its gallery are portraits of James P Joule William Spottiswoode Sir Joseph Hooker and Sir William Huggins while Sir Michael Foster is included in replica A portrait of the late Prof S H Vines hangs in the rooms of the Linnean Society

Mr Richard Inwards

VERY hearty congratulations are extended to Mr Richard Inwards who will reach the age of ninety four years this week (whilst yet happily in good health) having been born on April 22 1840 Elected into the Royal Astronomical Society so far back as 1861 he is we believe the oldest member of that body also of the Royal Meteorological Society whose ranks he joined a year later Early in life Mr Inwards became a mine manager in Bolivia and afterwards he acted in a like capacity in Spain for the Manganese Company Later on mining projects and enterprises led him to widely divergent places—to Norway Austria South America Mexico Settling in England meteorological studies became his prime interest and he was for nearly twenty years joint editor of the *Quarterly Journal of the Royal Meteorological Society* becoming in 1894 president of the Society serving the customary period Exactly forty years ago corresponding with the present month Mr Inwards read a paper entitled On Some Phenomena of the Upper Air A contribution (1907) The Metric System in Meteorology survived criticism at any rate for publication in the *Quarterly Journal* some will perhaps recall the discussion Mr Inwards is the author of Weather Lore and The Temple of the Andes , also he published (1911) an interesting reminiscent biography of W Ford Stanley F R A S in memory of that gifted mechanician responsible for many developments in the designs for mathematical drawing surveying and levelling instruments

A Broadcast from the Antarctic

THE B B C included in its programme on the evening of April 14 an interesting item which took the form of a short broadcast from Admiral Byrd s Antarctic expedition the main base of which is at Little America Bay of Whales in latitude 78° S The transmission was effected through the agency of the Columbia Broadcasting System of America, which has a representative with the expedition giving regular talks to listeners in the United States. The signals from the expedition's transmitting station at the Bay of Whales were received in South America, relayed to New York and thence to England and several other European countries. In addition to announcements by the representative mentioned above, members of the party gave a brief account of the prevailing meteorological conditions and of the scientific work being carried out by the expedition. The average daily temperature was stated to have been between −20° and −60° C., while a thirteen days' blizzard had been experienced recently. Admiral Byrd's advance party is located at about 123 miles nearer the South Pole than the main base at Little America. The brief programme included a musical item by members of the expedition and concluded with the singing of the British national anthem. Although reception was marred to some extent by distortion and a fairly high noise level, this broadcasting achievement showed in an interesting manner the possibilities of modern radio communication, and demonstrated that the isolation of polar expeditions is a thing of the past.

Broadcasting over Wires

At a meeting of the Wireless Section of the Institution of Electrical Engineers on April 11, a paper entitled "Principles of Audio Frequency Wire Broadcasting" was read by Mr. P. P. Eckersley. It is well known that too few wave-lengths are available for the purposes of wireless broadcasting, a limitation which makes it impossible to give all listeners both a variety of choice of programme and good quality reproduction. These limitations have stimulated an interest in alternative methods of distributing programmes to listeners, and broadcasting over wires has certain basic technical and economic advantages over wireless broadcasting. Wire broadcasting technique has been extensively applied in Holland, where 50 per cent of the Dutch listeners have their programme service laid on to the house by a wire connexion. Relatively slight developments of the same nature have taken place so far in Great Britain, although a number of companies are in operation for the re-diffusion of the ordinary wireless programmes.

The commonest form of such re-diffusion takes place at audio frequencies; the ordinary wireless broadcasting programmes are picked up by a receiver located where reception conditions are favourable, and the audio frequency output of this receiver is of sufficient strength to energise at once a thousand or more loud speakers connected to it by a line network. It is usual to connect each subscriber by two lines to this network so that a choice of two programmes is provided. Mr. Eckersley's paper dealt with the technical problems encountered in the design and construction of such a network in order to give a good quality service. An analysis was made of the effects set up by the interaction of the reactances and resistances composing the network and the loud-speakers, and it was shown that the received level, particularly towards the ends of the lines, varies with loading and frequency. Certain generalised rules have been evolved to indicate how the distortions incidental to this form of wire broadcasting may be minimised or even eliminated.

Commercial Production of Heavy Water

The recently discovered 'heavy water', which has created so much interest in popular as well as scientific circles, is to be produced commercially in England. Plant has been developed at the Billingham works of Imperial Chemical Industries, Ltd., which is capable of producing a continuous supply of heavy water of approximately 30 per cent purity at the rate of 5 gm. per day, while approximately pure 'heavy water' will be produced at a somewhat later date. I.C.I. anticipate that they will be able to meet any commercial demand that may arise. Urey and Washburn, in the United States, discovered that the residual water in old electrolytic cells contained a larger proportion of heavy hydrogen than the normal. It was further found that by continued electrolysis, the concentration of the 'heavy water' was enriched, ordinary light hydrogen being given off preferentially, and 'heavy water' accumulating. This gave the key to a successful method of preparing 'heavy water' in quantity, and the electrolytic method is the one in use at Billingham. Large-scale production of 'heavy water' is only possible where exceptional resources of power and raw materials exist together. At Billingham, not only ordinary hydrogen in large quantities, but also residues in which 'heavy water' has accumulated, are readily available. These resources, together with cheap power and convenient research facilities, make Billingham a logical centre for the large-scale production of the new compound. Since its discovery in the United States, its probable uses are becoming more evident, and it is eloquent testimony to the vitality of British chemical technique that in so short a space of time it should have been translated from a scientific curiosity to a marketable commodity.

The 24-Hour Time System

The British Broadcasting Corporation will adopt the 24-hour system of expressing time from April 22, when 'summer time' commences in Great Britain. The system will be used in all announcements over the microphone, in the journals published by the Corporation and in correspondence. No statement has been made as to the duration of the trial of the system, but it will doubtless be sufficiently long for the public to become thoroughly familiar with the system and for the extent of public approval or disapproval of the system to be gauged. As already announced in Nature, the Postmaster General will await the result of this experiment before coming to a decision on the question of the adoption of the system in the Post Office. It is proposed by the B.B.C. that a time such as 17 h. 15 m. shall be announced as 'Seventeen fifteen hours'. This terminology would be inaccurate and undesirable, and it is to be hoped that such a designation will not be used, otherwise this phraseology may soon become stereotyped The expression 'seventeen hours fifteen minutes' is accurate but long seventeen hours fifteen' is a contraction analogous to seventeen pounds fifteen' for £17 15s 0d But seventeen fifteen' (analogous to the present 5 15 p m, but with the now unnecessary p m dropped) should be quite sufficient At the exact hour, 17 hours can be used as simpler than 17 00

Origin of Tektites

THE suggestion first made in NATURE (131, 117, 1933) by Dr L J Spencer that tektites have been formed by the fusion of terrestrial rocks by the fall of very large meteorites has given rise to an interesting discussion, but, being unexpectedly novel, it has not met with general acceptance Prof F E Suess of Vienna, in whose classical paper of 1900 the name tektite was introduced and the meteoritic theory first proposed, has returned to the subject and he gives a recent review in *Die Naturwissenschaften* (21, 857, Dec 8, 1933) Here, and in a private letter, he admits that the Darwin glass of Tasmania may have been formed by the fusion of terrestrial material Some of the silica glass from the meteorite craters at Wabar in Arabia is, in fact, exactly like Darwin glass in every respect, and at both places the material is present in thousands of tons But from Tasmania no meteoric iron or craters have been recorded For other tektites (australites, billitonites, moldavites and indochinites'), Prof Suess still holds to the meteoritic theory He points out that they have a much wider distribution than the silica glass found around meteorite craters, and also that they usually bear no relation in chemical composition to the underlying rocks The same arguments are also put forward in a letter to the Editor from Mr T Hodge Smith, of the Australian Museum, Sydney, who has given an account of the tektites recently found in the Philippine Islands These arguments, however, overlook the fact that tektites are usually found in alluvial deposits and that they are often water worn and corroded, indicating that they have been transported from their place of origin In the case of australites found scattered on the surface of the ground over wide areas, it is conceivable that they have been transported by the natives

The 200 inch Reflector

IT was reported in the *Times* of March 27 that an accident had occurred during the pouring of the twenty tons of glass into the mould of the two hundred inch mirror for the new reflector for the California Institute of Technology Part of the mould came loose and floated to the top of the molten glass As soon as the pouring was completed, the cores were fished out of the molten mass According to a message issued by Science Service, Dr Hostetter, who was in charge of the operations, said that this mishap would not affect the success of the mirror, which has now been set aside to cool very slowly After the months of cooling have elapsed, it will take several years to grind the surface of the mirror Our readers will join with us in expressing the hope that it will be found that the incident of the break up of the mould will not have spoilt the present pouring of glass

Refrigeration Exhibition at the Science Museum

SIXTY years ago mechanical refrigeration was just coming into existence, and yet to day it is an essential part of everyday life, not only in its well known application to the transport and storage (including domestic storage) of perishable foodstuffs, but also in many of the industries upon which Great Britain depends Of its lesser known uses mention may be made of the manufacture of bread, biscuits, chocolate, margarine artificial silk stockings and cinematograph films, the brewing of beer, the curing of bacon, the refining of oil and the sinking of mine shafts and wells These are a few of about three hundred industries in which its use is either essential or in which it improves the quality of the product With the object of illustrating the part played by refrigeration and of showing the public the principles on which the several types of machines operate, a special exhibition has been arranged at the Science Museum South Kensington and will remain open until the end of August It consists mainly of models, working exhibits and demonstrations The exhibits have been supplied by the manufacturers and users of refrigerating machinery and the Museum has had the wholehearted co operation of the British Association of Refrigeration, the National Physical Laboratory and the Low Temperature Research Station A small Handbook has been prepared and will be on sale at the price of 6*d* (by post 7*d*) copies may also be obtained from H M Stationery Office Anyone who is interested in the subject may obtain from this Handbook in a concise form an idea of the modern science and practice of mechanical refrigeration the handbook also contains a brief outline of its historical development In addition, a bibliography on refrigeration has been prepared in the Science Museum Library and will also be on sale

Models of Tidal Estuaries

AT the Friday evening discourse held at the Royal Institution on April 13, Prof A H Gibson discussed 'Tidal Estuaries Forecasting by Model Experiments' During recent years much work has been done on models reproducing the flow of water over weirs, through sluice gates, etc, and it has been found that, if suitable precautions are taken, the model results give a reliable indication of the behaviour of the original River flow models are now being extensively used to investigate the erosion and deposition of bed materials and the effect of works designed to improve the navigable channel The technique of such investigations is not yet fully developed, different methods being used in different laboratories Chronologically, models of tidal estuaries were used before those of uni flow rivers, the first tidal models (of the Mersey Estuary) having been constructed by Osborne Reynolds in 1885

In 1926 the Severn Barrage Committee of the Department of Civil Research decided to carry out investigations on a working model of the Severn Estuary with the view of determining the probable effect on the physical and hydrodynamical features of the estuary of the introduction of a barrage for generating tidal power at the English Stones between Beachley and Avonmouth This model was constructed and operated in Prof Gibson's laboratory

PROF GIBSON dealt with the problems involved in the construction and operation of such models and with a comparison of the results obtained from the Severn model with those observed in the estuary The successful use of a model depends largely on its being of a suitable scale and on the possibility of being able to reproduce with reasonable accuracy the physical conditions tending to produce movement of the bed materials This is more easily accomplished in an estuary having well defined physical characteristics with a large tidal range in which the action of the ebb and flood currents are all important In such a case experience shows that the behaviour of the model reproduces closely that of the estuary In other types of estuary having comparatively small tidal ranges and especially if very exposed to gales the results are mainly likely to be of value in so far as they enable the effect of any training works on the set and velocity of the currents and on the tidal range and period to be determined

Close of Excavations at Ur

WITHIN a few days of the publication by the British Museum of the volume reporting on the excavation of the Royal Tombs at Ur Dr C Leonard Woolley in the *Times* of April 13 announces the close of the brief season's work and with it the end of the joint expedition of the British Museum and the Museum of the University of Pennsylvania to Mesopotamia For twelve years this expedition has been engaged in an excavation which has produced results comparable in their far reaching effect on archæological studies with the epoch making discoveries of Sir Arthur Evans in Crete The results reported by Dr Woolley in what all will regret to know is his final dispatch in the long series he has contributed to the *Times* since 1922 form a fitting and impressive climax to what has preceded The main objective of the season was the discovery of a cemetery of the early Jemdet Nasr period for which the search in default of guiding indications was in the nature of an act of faith It was abundantly justified by the discovery after prolonged and strenuous digging of a stratum of 10 ft containing burials in the upper levels of which the characteristically flexed human skeletons were surrounded by large numbers of stone jars in a variety of forms and material One grave alone contained thirty three vases In the upper range the stone vase had entirely ousted that of clay As Dr Woolley remarks it was a luxury that had become a commonplace As Ur stands in a stoneless land and the material had to be brought from either the north of Mesopotamia or from the area of the Persian Gulf it would be difficult to find a more impressive testimony than this closing discovery to the early accession of Ur to wealth and importance of which Dr Woolley's excavations have afforded cumulative evidence year by year

SINCE the trial excavations made by Dr R Campbell Thompson at the end of the War for the purpose of a report to the British Museum and the more or less tentative expedition of the late Dr H R Hall to Ur and Al Ubaid before Dr Woolley began systematic excavations in 1922 the archæology of the Middle East has advanced far and fast Stimulated by Dr Woolley's results expeditions have worked at Kish Nineveh Arpachiyah Tell Asmar and elsewhere each site helping in the work of amplifying and elucidating material which in the long run it is not unfair to say gains its full significance by reference to the evidence from Ur and the outline of early Mesopotamian history which that site has afforded It will be some time perhaps years before the place of Ur in archæological studies will have attained its final adjustment Possibly from this point of view it may be no bad thing that further discovery here has ceased for the time being affording an opportunity for comparison and reflection Results must be weighed and pondered they must be brought into closer relation with what has been done on the fringes of this great archæological province It may then appear that by no means the least important outcome of the broader view now taken of the archæological field of which Ur has been made the centre has been its bearing on the discovery of the prehistoric civilisation of the Indus Valley This discovery would never in almost any circumstances have been passed over as unimportant but the systematic examination of the site and its interpretation would have been far different and certainly less fruitful had it been made before instead of after the early excavations at Ur Archæologists indeed owe a deep debt of gratitude to those who have taken part in the work of the expedition with Dr Woolley at their head and to the institutions by which the joint expedition has been supported

Jubilee of the Society for the Study of Inebriety

THE fiftieth anniversary of the foundation of the Society for the Study of Inebriety and Drug Addiction and the centenary of the birth of its founder Dr Norman Kerr who died in 1899 were celebrated on April 10 by a luncheon held at the Langham Hotel at which the Minister of Health Lord D'Abernon the Bishop of Norwich Sir Thomas Barlow the presidents of the Royal College of Surgeons and of the Royal Society of Medicine and Sir Josiah Stamp were the principal guests The luncheon was followed by a commemoration address delivered by the president Sir Humphry Rolleston who gave a sketch of the life of the founder and the activities of the Society Norman Kerr who was the author of numerous works on various aspects of the alcohol problem regarded inebriety as a disease essentially allied to insanity and insisted that it should be treated medically and not as if it were a crime. It was mainly due to him that the Habitual Drunkards Act of 1888 and the Inebriates Act of 1898 were amended. During the fifty years of its existence, the subjects discussed by the Society have included the influence of heredity on alcoholism, alcoholism and child welfare, alcoholism and venereal disease, the use of alcohol in medicine, drug addiction as an international problem, ether-drinking and the cigarette habit. The Society, which consists of medical members and lay associates, aims at a scientific study of alcoholism and drug addiction and has not a policy of total abstinence.

Society of Dyers and Colourists

ARRANGEMENTS for the jubilee celebrations of the Society of Dyers and Colourists, to be held at Bradford at Whitsuntide, are in active progress. Inaugurated at a meeting in Bradford on May 14, 1884, the Society is the oldest of its kind in Great Britain. Special interest in the celebrations will be attached to the issue early next month of a jubilee number of the Society's *Journal* containing original articles by eminent authorities on the processes of dyeing and their development in the course of the past fifty years. In these, invention, scientific research and records of practical applications will receive full attention. It may be recalled here that the Society allots the Perkin Gold Medal at intervals, for conspicuous service to the tinctorial industries. By means of its award the synthesis of indigo, the discovery of viscose, of primuline, and of alizarine blue have been severally recognised.

Geistige Arbeit

THE object of a new periodical of this title which appears twice monthly (25 pfennigs per copy) is to give brief reviews of the progress and tendencies of modern scientific research. The subjects considered cover a wide field, including anthropology, political economy, agriculture, sociology and all the pure and applied sciences. There are articles on peasants and nomads, problems of German sociology, new concepts of natural science, methods of counting for statistical purposes, Paracelsus (a sketch), and many others. The contributors are chosen from the ranks of those who have done original work in their respective fields. In the article by Möglich dealing with the foundations of present day physics, we find due acknowledgment paid to the epoch making ideas of Planck and Heisenberg, but there are important omissions which detract from the value of the account. In highly compressed articles of this type, it is of primary importance that the authors should have not only a deep insight into their subjects but also a proper sense of values, if the services of a discriminating censor are not to be invoked. Goethe has said: "Die Vernunft ist auf das Werdende, der Verstand auf das Gewordene angewiesen." This remark applies particularly aptly to the present journal, which bears the sub-title "Zentralblatt für die gelehrte Welt". The article on Theophrastus Bombastus von Hohenheim, commonly called Paracelsus, is of interest as his name has recently come into prominence again as one of the first great experimenters in medical science—one hears of a Paracelsus Renaissance in Germany—in spite of a certain notoriety as a vagabond miracle worker which he probably only partly deserved. His ideas, if not actual results obtained, undoubtedly exerted a considerable influence on later workers. The journal is published by Walter de Gruyter and Co., Berlin W 10, Genthinerstr. 38.

Philosophy of Science

THE welcome co-operation between science and philosophy, which has become a distinctive feature of our time, is further illustrated by the appearance of a new quarterly *Philosophy of Science* which is published by the Philosophy of Science Association in the United States (Baltimore: Williams and Wilkins Co.; London: Baillière, Tindall and Cox. 6s. 9d.). This interesting publication sets itself the useful task of giving an organised expression to the growing interest among philosophers and scientific workers in classifying, and perhaps unifying, the programmes, methods and results of the disciplines of philosophy and of science. With this object in view the editor, Prof. W. M. Malisoff, proposes as a research programme the analysis of meaning, symbolism, definition, axioms and postulates, the study of the nature and formulation of theoretical principles, and questions of method and of the structure and hierarchy of the sciences. The first issue of the new journal contains a remarkable series of papers; among the contributors are Prof. J. B. S. Haldane on "Quantum Mechanics as a Basis for Philosophy", D. J. Struik on "The Foundations of the Theory of Probabilities", Rudolf Carnap on "The Character of Philosophic Problems". The excellent presentation of the journal and the eminence of its contributors give an added value to its object and method which, no doubt, will appeal equally to scientific workers and to philosophers.

Research in the Solomon Islands

A REPORT on the work of the Templeton Crocker Expedition to the Solomon Islands, 1933, has recently been sent to NATURE by the Director of the Bernice P. Bishop Museum, Honolulu. The expedition left San Francisco on March 2, 1933, in Mr. Templeton Crocker's auxiliary schooner *Vaca* and returned on September 15 after conducting a preliminary ethnographical and medical survey of a number of islands in the Solomon group. The principal objective was the Rennell and Bellona islands, but before arriving there the expedition collected data bearing on tuberculosis and tropical diseases, as well as ethnographical material, at Sikiana, Tulalagi, Guadalcanar and Malaita. Advantage was taken of conditions on Rennell and Bellona, where bird and insect life are undisturbed and the inhabitants virtually unaffected by European contacts, to make extensive collections of birds, plants and insects and to record particulars relating to native life and customs, which appear to have suffered little change since the Polynesian ancestors of the inhabitants first arrived there twenty generations ago. It was also possible to arrange for an intensive study of the disease and general health of the population of one district. Blood samples for filaria tests and blood groups were obtained. On Bellona the party was fortunate enough to obtain cinematograph record of the annual first fruits ceremony. A medical and health survey was also made on the islands of San Cristobal, Santa Anna and Santa Catalina. As a result of the expedition's work, 3,200 artefacts have been added to the collections of the museum in Honolulu [illegible] as a large number of entomological and botanical specimens. Other collections are to be distributed among scientific institutions in America and Europe, while the material relating to canoes will be submitted to Dr. A. C. Haddon in Cambridge.

Regulations Concerning Chemicals

ACTS of Parliament and Statutory Rules and Orders affecting the chemical industry are sufficiently numerous and complex to require documentation in a convenient and easily accessible form. That task has been undertaken by the Association of British Chemical Manufacturers, which in January 1931 published an index of such information. The third supplement, covering acts, rules and orders which have come to the notice of the Association during 1933 has recently been issued (Heffer, Cambridge, 6*d.* post free). New regulations regarding the packing and stowing of dangerous goods in ships have been made, and a revised edition of the summary of the principal regulations made under the Explosives Act has been issued. Reference is made to the Spirits Act, 1880, and the Still Licence Act, 1849. All plant capable of being used as a still is subject to licence, but exemptions are granted in respect of alkali works, coal gas, tar distillation, solvent recovery, chemical experiments, professional chemists, etc. Water stills of more than 1 gallon capacity require a licence; otherwise exemption may be granted on application. The supplementary index also refers, *inter alia*, to the Dyestuffs (Import Regulation) Act, the Import Duties Act, the Ottawa Agreements Act, the Poisons and Pharmacy Act, and the Safeguarding of Industries Act.

Graph Papers

WE have received from Messrs. Wightman Mountain, Ltd., of Artillery House, Victoria Street, Westminster, some samples of graph paper. These are of considerable interest as exhibiting the great range and variety of papers now produced in England. Of squared papers alone, Messrs. Wightman Mountain list more than 250 sizes and styles, some with ruled and others with engraved lines. A wide range of logarithmic papers includes, for example, sheets covering the ranges 7–400 and 1–10,000. Profile paper is specially ruled for making longitudinal sections of railways, roads, etc. Other varieties of graph paper include permille paper (arithmetic probability), square law, polar, isocandle, triangular and isometric papers. A new paper is one ruled in tenths of an inch one way and in inches and twelfths the other. The increasing demand for the graphical presentation of commercial data has led to the publication of a number of data sheets, including daily, weekly and monthly progress sheets. Even a holiday chart is not lacking. To furnish some idea of the papers available, the firm is offering for half a crown a special sample packet of 58 different data sheets.

International Agricultural Congress in Budapest

THE International Congress of Agriculture is meeting this year in Budapest on June 13–20. The Congress is held every two years in a different European capital and is attended by delegates from some thirty countries who represent every side of agricultural life. The work of the Congress is divided into eight sections. The first deals with economics and agrarian policy, world prices, the organisation of markets and the economic consequences of mechanisation. Two other sections, those on co-operation and agricultural industries, occupy parts of the same field, and the section dealing with viticulture will this year be economic rather than technical. Two sections treat respectively of animal and vegetable production from the scientific side. Modern horse breeding, the influence of pasture on the quality of milk, contagious abortion, the production of forage crops under semi-desert conditions, plant selection, the classification of wheats and the improvement of alkaline soils are the principal subjects for discussion at Budapest. The remaining sections are to some extent social in scope, dealing with agricultural instruction and the position of women in rural communities. The Congress will be accompanied by social functions and followed by excursions, which will enable delegates to see something of educational and scientific work in connexion with Hungarian agriculture, as well as of Hungarian farming and peasant life. It is expected that a party of British delegates, connected either with agricultural science or with bodies such as the National Federation of Women's Institutes, will take part. Further information can be obtained from the secretary of the British Corresponding Committee, International Congress of Agriculture, 10 Doughty Street, London, W.C.1.

Announcements

PROF. J. C. MCLENNAN will deliver the twenty-fifth Kelvin Lecture before the Institution of Electrical Engineers on April 26, taking as his subject "Electrical Phenomena at Extremely Low Temperatures". Before the lecture, the Faraday Medal of the Institution will be presented to Sir Frank Smith.

DR. C. E. KENNETH MEES, director of research to the Eastman Kodak Co., Rochester, U.S.A., will deliver the Sir Henry Trueman Wood Memorial Lecture before the Royal Society of Arts on May 16. The subject of Dr. Mees's lecture will be "Some Photographic Aspects of Sound Recording".

A DINNER in honour of Prof. Karl Pearson will be held at University College, London, on April 23, when a portrait plaque in bronze of Prof. Pearson will be presented to the College on behalf of subscribers to the Karl Pearson Commemoration Fund. A Brunsviga calculating machine has already been handed over to Prof. Pearson and a duplicate of the plaque will be given to him at the dinner.

THE Gold Medal of the Institution of Mining and Metallurgy, the highest distinction in its power to confer, has been awarded to Mr. John A. Agnew, in recognition of his services in the development of the mineral resources of the Empire, and to the mining industry. The following awards have also been made by the Council of the Institution: The Consolidated Gold Fields of South Africa Ltd. Gold Medal and premium of forty guineas to Dr. W. R. Jones, for his researches on the incidence of silicosis, and for his published papers on the subject; William Frecheville Student's Prize of ten guineas to Mr. D. J. Rogers, for his "Notes on a Tunnel driven at Stan Trg Mine, Yugoslavia"; two grants from the Post-graduate Grants Fund to enable the recipients to pursue their geological studies in Spain.

MR. K. F. TOMS, late assistant superintendent of plantations, East African Agricultural Research Station, Amani, has been appointed by the Secretary of State for the Colonies to be agricultural and forestry officer, St. Helena.

AT the stratosphere conference, which closed in Leningrad a few days ago, it was decided to call a world conference for the study of the stratosphere in the U.S.S.R. in 1936. The time of the conference is to coincide with the eclipse of the sun on June 19 of that year.

THE applications of photography to map making are steadily widening. The fourth International Congress of Photogrammetry will be held in Paris on November 16–December 2 this year. There will be an exhibition of materials and apparatus relevant to the Congress at the same time. Inquiries should be addressed to M. le Président, Commission 2, Congrès International de Photogrammetrie, 4 Rue Galilée, Paris 16 e.

THE Rome correspondent of the *Times* reports that Commendatore Renato Donati on April 11 at the airport of Montecelio broke the world's altitude record for aeroplanes of any type when he reached a height of 14,500 metres. Signor Donati was flying a specially constructed Caproni 114 h.p. biplane.

AT the meeting of the London Mathematical Society to be held on Thursday, April 26, at 5 p.m. in the rooms of the Royal Astronomical Society, Burlington House, W.1, there will be discussion on "Integral Functions". Prof. E. C. Titchmarsh will introduce the subject, Dr. E. C. Collingwood will speak on "Properties of Exceptional Values of Integral and Meromorphic Functions", Miss M. L. Cartwright on "Directions of Borel of Integral Functions and their Relation to the Singularities of Power Series", and Prof. J. M. Whittaker on "Difference Properties of Integral and Meromorphic Functions".

WE have received a volume of Abridged Scientific Publications from the Kodak Research Laboratories, vol. 15, 1931–32, published by the Eastman Kodak Company, Rochester, New York. This volume comprises abridgments of 61 papers, most of which are accounts of original researches on subjects related to photography.

THE Ministry of Agriculture has recently issued a portfolio of "Leaflets on Insect Pests of Farm and Garden Crops" which is intended to replace sectional vol. 11 on the same subject. The advantage of the present portfolio over the bound sectional volume is that it enables all new and revised leaflets to be inserted and the portfolio is thus kept up to date. The portfolio of leaflets is obtainable price 1*s*. 6*d*. net through any bookseller. Readers who wish to receive copies of new or revised leaflets may do so on payment of a nominal registration fee; full particulars of this scheme may be obtained by writing to the Ministry of Agriculture and Fisheries, 10 Whitehall Place, London, S.W.1.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A technical officer (Grade II) in the Directorate of Technical Development, Air Ministry—The Chief Superintendent, Royal Aircraft Establishment, South Farnborough, Hants (April 23). A lecturer in educational psychology at the Maria Grey Training College, Salusbury Road, London, N.W.6—The Principal (April 24). Three male junior assistants (temporary) at the Experimental Research Station, Porton, Wiltshire—The Chief Superintendent, Chemical Defence Research Department, 14 Grosvenor Gardens, S.W.1 (April 28). A demonstrator in biochemistry in the School of Biochemistry, University of Cambridge—Sir F. G. Hopkins, Sir William Dunn Institute, Tennis Court Road, Cambridge (May 2). A temporary technical assistant in farm economics in the Department of Agriculture for Scotland—The Establishment Officer, Queen Street, Edinburgh, 2 (May 5). An assistant master to teach mathematics, mechanics and physics at the Polytechnic, Regent Street, London, W.1—The Director of Education (May 7). An assistant lecturer in botany at the University of Manchester—The Registrar (May 7). A chief inspector of explosives in India—The High Commissioner for India, General Department, India House, Aldwych, London, W.C.2 (May 10). An assistant lecturer in zoology at the University of Bristol—The Registrar (May 11). A lecturer in zoology at Bedford College for Women, Regent's Park, N.W.1—The Secretary (May 22). A fuel technologist in the Public Service Board of New South Wales—The Official Representative of the Government of New South Wales, Wellington House, 125, Strand, London, W.C.2 (May 31). A member of the vocational guidance staff at the National Institute of Industrial Psychology, Aldwych House, London, W.C.2—The Secretary.

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Co-ordination of State Scientific Services

THE editorial article on "Co-ordination of the State Scientific Services" in NATURE of February 10 comments upon various statements made in "Patriotism Ltd."

For example, the article states that since the War period, the D.S.I.R. and the M.R.C. have not undertaken or financed any work for 'purely warlike purposes' and implies that 'purely industrial or medical motives' have been the primary aim in all their investigations. Furthermore, the article states: —

"It would be equally indefensible if work undertaken at the instigations of the fighting services but not specially paid for by contributions from their vote were not published and made available for use in industry."

In the case of the following three investigations carried out by the Medical Research Council, reports were sent only to departments of the fighting services and were not published:

(1) The Council investigated a problem of direct importance to chemical warfare, namely the limiting of the visual field for different types of respirators. This investigation was carried out at the request of the Chemical Defence Research Department and the results were reported to that Department only.

(2) The Industrial Health Research Board investigated "the personal factors in proficiency for naval gunnery". Is it seriously maintained that this has an industrial application?

(3) The same Board, at the request of the Admiralty, investigated the psychological factors in deep sea diving and sent its report to the Admiralty.

In all these cases the investigations appear to have been financed by the M.R.C., yet the reports are not recorded as having been published.

The M.R.C. investigations into rifle shooting were reported to the War Office and no report seems to have been given to the general public. It is incorrect to suggest that the Council has drawn on the special acoustical knowledge of the fighting services primarily to assist in the alleviation of deafness, since it undertook "at the request of the War Office" investigations into the selection and training of anti-aircraft listeners. These investigations were reported as being continued in the M.R.C. Annual Report for 1931–32, but all reference to them is omitted from the Report for 1932–33.

In view of these facts and of many similar ones published in 'Patriotism Ltd.', we must conclude that a considerable amount of assistance has been given to the fighting services by these committees. We agree that in practically all branches of science, under the control of these committees, new knowledge is adaptable to the purposes of military science. It seems, however, to be indisputable that such adaptation is the proper function of the soldier and of his scientist servants. It is known that there have been certain resignations and a protest against this employment for warlike purposes of presumably neutral scientists' time and energy.

The statement made by the president of the Royal Society that scientific men "are now in real control of scientific policy in Great Britain" greatly clarifies the position. As you valuably state, further militarisation of these research committees can take place only with the scientists' "connivance and responsibility".

DOROTHY WOODMAN.

Union of Democratic Control,
34, Victoria Street,
London, S.W.1.
March 15.

"PATRIOTISM LTD.: an Exposure of the War Machine" is published by the Union of Democratic Control, and Chap. 5, entitled "The Science of Murder", is intended to show how such organisations as the Department of Scientific and Industrial Research, the various industrial research associations, the Medical Research Council and the Industrial Health Research Board, "are perverted to the uses of death". The main contention is that research is carried out for the fighting services by these bodies though their financial resources are budgeted for in the civil estimates. After an inquiry into the facts, these and related allegations were dealt with in the article in NATURE to which Miss Woodman refers. When the article appeared, we received a long communication in which an attempt was made to justify the statements in "Patriotism Ltd.", but we could not possibly find space for it, and therefore we asked Miss Woodman to limit herself to specific examples of the diversion of financial provision for civil research to work for the fighting services. The above letter is the result, and the very triviality of the cases cited is almost enough to condemn the main thesis.

It is scarcely worth while to traverse the arguments again, but in any government department concerned with scientific research it may be taken for granted that: (1) Its financial resources will not be available for work which should be paid for by another department. (2) If work is done at the suggestion of another department, or with facilities given by it, a report is usually transmitted to the department. (3) If the results are not published, this is not because of any seal of secrecy but because they are incomplete or not of sufficient scientific value to be published.

As to the particular investigations mentioned by Miss Woodman, we suggest that if the Union of Democratic Control had desired to know the truth concerning them it would have communicated with the Medical Research Council instead of construing for itself isolated sentences in reports. We have inquired into these cases, and have satisfied ourselves that the facts are as follows:

1. The Physiology of Vision Committee of the M.R.C. was consulted on the effect of respirators on the visual field. The only work done on the subject was undertaken by a member of the Committee who is an officer of the R.A.M.C., as stated in the Annual Report of the M.R.C., and as he was giving whole-time service to the War Office, the M.R.C. was not involved in any expenditure. Any knowledge gained by the committee remains, however, available when advice is asked as regards respirators used in dangerous industries, mine rescue work and the like.

2. It is certainly maintained that the investigation of the personal factors in proficiency for naval gunnery has an industrial application. It formed part of a larger investigation into the general problem of vocational selection. Many of the opportunities

for this work have been found in the Services where it is possible to examine a controlled personnel and to obtain at a later date reliable records of their after histories Few of the results have yet been published but all are available for publication eventually when enough evidence has been accumulated

3 The main part of the work on deep diving done by the M R C was on the fundamental question of the saturation of the tissues with gaseous nitrogen The report on this work forwarded to the Admiralty consisted of three sections each of which has since appeared in the *Quarterly Journal of Experimental Physiology* The work done on the psychological side occupied only a very small fraction of the time and as nothing of importance emerged from it no report has yet been published though the knowledge gained is available to anyone inquiring about deep diving from a civilian point of view

4 The investigation of rifle shooting was not undertaken at the request of the military authorities but at the instance of an academic psychologist who happened to see in the operation an interesting combination of manual visual and psychological factors The results have not been published, but they are being prepared for publication The War Office was sent a report as a matter of courtesy

5 In the matter of the selection and training of anti aircraft listeners the actual investigations made by the M R C have taken the form of fundamental research into questions of aural localisation and the results have been or are being published

We need scarcely say that no further space can be afforded in these columns for a discussion of the questions raised by the Union of Democratic Control as to the use made by the fighting services of civil research organisations

EDITOR OF NATURE

Proportion of Heavy Water in Natural Water

IT has been suggested that the proportion of heavy water in natural waters may vary according to their source It is, however, unlikely that any considerable variations occur

Consider for example, the Dead Sea We may suppose that the rate of influx of water into the Dead Sea is equal to the rate of loss by evaporation In a case like this a steady state will eventually be reached—and in the case of the Dead Sea, presumably has been reached—such that the proportion of heavy water in it remains constant with time At the steady state, the composition of the inflowing water is the same as that of the water vapour evaporating away So the Dead Sea is in equilibrium with water vapour of the same composition as the inflowing water, and, in consequence, it contains but a very slightly greater concentration of heavy water than the inflowing water In fact, the excess is no more than would be gained by a single distillation at a pressure equal to the vapour pressure of the Dead Sea—a negligibly small amount

This argument assumes that the inflowing water is at once distributed evenly throughout the whole of the Dead Sea Imperfect mixing will permit of a greater concentration of heavy water, but it is unlikely even then that there is any remarkable concentration of heavy water in water from any natural source We may take it, then, that natural waters contain a sensibly constant concentration of heavy water, or, to speak more cautiously that the processes of evaporation and condensation in Nature are unlikely to produce any considerable separation of the two kinds of water

H A C McKAY

33 New Road
Croxley Green
Herts
March 27

IN connexion with the foregoing letter some results may be quoted of an examination of Dead Sea water carried out in this laboratory by Dr A F Martin

The Dead Sea water was obtained by the kindness of Palestine Potash Ltd and consisted of samples taken from near the surface and at a depth of 53 metres below the surface

These samples were distilled and in addition the salts remaining after ordinary distillation were reduced to dryness by the application of heat, but none of the distillates was found to be heavier than ordinary pure distilled water prepared in the laboratory

To determine the density, a spherical mass of silica attached to the beam of the balance by a fine silica fibre was weighed in the various samples of water and the greatest difference in density between distilled water and distilled Dead Sea water was 0 00003 the uncertainty of measurement being about 0 00002

It does not appear therefore that there is any notable proportion of heavy water in the Dead Sea

Spectrum of the HD- and D_2-Molecules

WE have photographed the molecular spectrum of hydrogen under high dispersion and obtained a series of photographs of samples with increasing amounts of the heavy isotope ranging from pure H_2 to practically pure D_2 We are indebted to Prof H S Taylor of Princeton for the heavy hydrogen In this way it was possible to decide unambiguously whether a line is due to H_2 HD or D_2 It is well known that a considerable part of the H_2 spectrum was analysed chiefly through the efforts of O W Richardson and his co workers but there remains a great number of problems concerned with the analysis and interpretation of this complicated spectrum The main purpose of the present investigation is to obtain additional material which can be used for a further analysis of the molecular spectrum of hydrogen and to help to clear up doubtful points in its interpretation We are confident that in this way our knowledge of the structure of the hydrogen molecule can be greatly increased

The comparison of the three spectra gives indeed a vast amount of interesting information for which we must however refer to the full account of the work which is to appear elsewhere We wish to give here only some of the results of the analysis of the bands of HD and D_2 which are analogous to the Fulcher bands of H_2 These bands have a relatively simple structure and do not show markedly the decoupling effects which are so characteristic of most other hydrogen bands Therefore most of the results of the analysis can be summarised by a table of the band constants

	1 H_2	2 HD	3 D_2	*Ratio* 1 2	 1 3	ρ^n_{12}	ρ^n_{13}	n
ω	2373 18	2055 52	1678 70	0 866 15	0 707 37	0 866 17	0 707 44	1
ω''	2665 34	2308 39	1885 80	0 866 08	0 707 53			
ωx	66 32	49 68	32 90	0 7490	0 4960	0 7502	0 5005	2
$\omega x''$	72·09	53 73	35 93	0 7454	0 4985			
B''	34 216	25 685	17 109	0 7507	0 5000			
α''	1 671	1 099	0 606	0 658	0 363	0 650	0 354	3
D''	0 0216	0 0128	0·0055	0 59	0 25	0 563	0 250	4

In this table the chief constants which occur in the expression

$$W/hc = \omega v - \omega x v^2 + \quad + B(1 \quad \alpha v)J(J+1) - DJ^2(J+1)^2 +$$

$(v = \frac{1}{2}, 1\frac{1}{2}, \quad , J = 0\ 1, 2, \quad)$ for the vibrational and rotational energy are given for the upper and lower states of the three different hydrogen molecules The values for H_2 are taken from the work of Richardson and Das[1] The columns marked '*Ratio* give the ratio of the constants of HD and D_2 to the corresponding values for H_2 The next two columns give the theoretical values to which these ratios should be equal These are found from the known[2] values of the reduced masses μ_i by the relations $\rho^2_{ij} = \frac{\mu_i}{\mu_j}$

It is seen that the agreement between the theoretical and experimental ratios is very satisfactory We are confident that the remaining discrepancies are entirely due to experimental errors which arise chiefly from the fact that an inadequate formula is used for the calculation of the constants (We included terms up to the fourth power in v and to the sixth power in J) The agreement can be materially improved by an adjustment of the constants without impairing the accuracy with which the observed wave numbers are represented by the formulæ We prefer, however, to give here the constants which were calculated without bias in the usual way for each molecule separately The table then shows to what accuracy the calculated values for band constants of this type in general can be expected to agree with the theoretical values The fact that a given formula represents well the experimental data is very often insufficient to judge this point

We find that there is a discrepancy of about 2 6 cm^{-1} between the values of the electronic frequencies This seems too large to be attributed entirely to experimental errors We wish to suspend our judgment about this, however, until all the constants have been recalculated in a way which takes more rigorously into account all the various relations between them

The component of the initial $^1\Pi$ state which gives the P and R branches shows perturbations for all three molecules The type of perturbation is the same, and is most easily recognised by the anomalous values of the Λ doubling The details, however, differ considerably While, for example, in H_2 the state with $v = 1$ is most strongly affected, it is quite regular for HD, but for this molecule the $v' = 0$ level is very irregular This behaviour can be understood from the fact that the relative positions of the perturbing and the perturbed vibrational levels are slightly shifted in the three different molecules due to the anharmonic character of the binding

Richardson and Das noticed that in H_2 all P- and R branches are absent for $v' > 4$ This is also true for HD, but in D_2 the P and R branches are normal for $v' = 4$ whereas they are absent for $v' > 5$ We can understand this behaviour if we attribute the disappearance of these branches to predissociation The predissociation limit, which is determined entirely by the shape of the potential curves, is independent of the nuclear masses, and while it is surpassed by four vibrational quanta of H_2 and HD, four of the smaller vibrational quanta of D_2 will fall below it, but five will also surpass it for this molecule From these observed facts we can derive that the predissociation limit must lie between 0 93 and 1 02 volts above the electronic frequency of the $^1\Pi$ state

Activities of Life and the Second Law of Thermodynamics

I AM anxious to treat Prof Donnan's views with all courtesy, but think his last letter, written in conjunction with Prof Guggenheim, is entirely invalidated, like his previous letter, by a technical error in thermodynamics

The ordinary formula for the positional entropy of a large number of particles is

$$-k \iiint \nu \log \nu \, dx\, dy\, dz$$

where ν is the number of particles per unit volume Thus moving N particles from a place of density ν to one of higher density ν' decreases the entropy by

$$kN(\log \nu' - \log \nu)$$

Surely Profs Donnan and Guggenheim have overlooked the factor N Owing to its presence, moving a single molecule does not, as they contend, have the same effect as moving a truckload of N molecules, but only $1/N$th of this effect The same error, I think, invalidates their second paragraph

It is difficult to discuss views based on arguments which seem to me so entirely fallacious, so I can only repeat that I think the writers are in error by more than mere technical mistakes They seem to me to be comparing two things that do not enter into relation with one another at all—like the number of calories in a man's dinner, and the number of ergs needed to carry it in from the kitchen to the dining room

As they ask for a physiological reference, may I (although no physiologist) refer them to Carnegie Institution Publication, No 446 ("Mental Effort", by F G and C G Benedict, 1934) ?

Periodic Structure in Ice

A CONCAVE metal vessel, 5 cm × 3 75 cm × 1 2 cm at its deepest point, resting in natural contact (that is, at greatest convexity of its convex surface) with a stone pavement, became filled with rain water or melted sleet It remained overnight, and held next morning a plano convex lens of ice, which exhibited a beautiful periodic structure

The periodic structure consisted of about a dozen very distinct colourless concentric circles, 0 5–1 mm radial variation, the least, central, one about 1 cm diameter, with transparent ice between the rings The structure persisted through the depth of the lens, the largest circle being, of course, of least depth A small piece of black foreign matter (perhaps a smut) which may, or may not, have had something to do with the formation of the structure, was frozen into the centre of the smallest circle

In reporting a previous observation of periodic structures in carbon films due to oil drops[1], the absence of colloids, chemical action and dissolution was stressed But in this present observation, which also is probably original, one chemical substance alone appears to be concerned There is, of course, the possibility of 'heavy' water and of two phases—solid and liquid—being concerned, though the ring structures seemed as solid as the clear ice The original liquid might also have contained a slight amount of dissolved impurity, if only condensation nuclei Attempts will be made, artificially, to reproduce such periodic structures in ice

Loss of Mass in Binary Systems

SOME years ago, Sir James Jeans[1] considered the problem of the variation in the orbital elements of a binary star in which one or both of the components is losing mass by radiation He concluded that, in these circumstances, the orbital eccentricity will remain constant, whereas the semi axis major varies inversely as the sum of the masses of the components

Shortly after, Prof E W Brown[2] discussed the same problem from a different point of view, arriving at the conclusion that the orbital eccentricity varies inversely as the sum of the masses, while the semi-axis increases at a still higher rate His paper was criticised by Jeans[3], but the cause of their fundamental disagreement was not then, nor has since, been cleared up

An investigation which has recently been completed throws light on this difficulty Starting from the equations of motion in Cartesian form as given by Jeans, the differential equation of the orbit is deduced, and its general solution obtained It is found that Jeans's result is justified, and the source of Brown's error is explained

The *main* result *of the investigation is* that the loss of mass through radiation leads to the relation, ***semi-axis major is inversely proportional to the mass of the system***, which holds throughout the life of the binary, or alternatively,

$$P/a^2 = \text{constant},$$

that is, $\log P - 2 \log a'' + 2 \log \pi'' = \text{constant}$ in the usual notation

A statistical study of all the available material for the visual binaries has shown that not only does this relation hold throughout the life of any one star, but also it holds statistically at the present epoch for all visual binaries in the form

$$\log P - 2 \log a'' + 2 \log \pi'' = -0\ 826 \pm 0\ 098$$

This result shows that all such binaries apparently originate with nearly equal values of the quantity P/a^2, the degree of scatter of individual values from the mean being given by the probable error 0 098 of the constant 0 826

This relation leads to a form of hypothetical parallax which we may call the mass radiation parallax, and which has been computed for 123 binaries the orbital data of which can be taken as well determined The computed values are found to agree very well with those found on the basis of other methods

The above relation does not appear to hold for the eclipsing or the short period spectroscopic binaries The reason for this difference between the short and the long period binaries is probably bound up with the difference in origin of these two groups, but as yet no adequate explanation of the observations has been forthcoming

Calcium Isotope with Mass 41 and the Radioactive Half-period of Potassium

THE values given in a previous note[1] for the radio active half period of the potassium isotope with mass 41, as derived from the abnormality in the atomic weight of calcium extracted from Rhiconich and Portsoy pegmatites, stand in need of correction

In the first place, it has been learned through the kindness of Prof Arthur Holmes, of the University of Durham to whom a sample of the Rhiconich rock had been sent, that the Geological Survey analysis of this pegmatite[2] was not applicable to the material actually used, which had not been hand picked Independent analysis conducted by Dr Winifred Guthrie in this laboratory and by Dr A W Groves of the Royal College of Science agreed in assigning to this material a CaO content of 0 55 per cent (instead of 0 27) and K_2O content of 8 0 per cent (instead of 9 35)

The Portsoy pegmatite, which had been hand picked, gave analyses much closer to the Geological Survey figures, namely, CaO 0 28 per cent (exact agreement) and K_2O 8 0 per cent (instead of 8 9) The age of 600 million years assumed for this rock in our previous note, however, is decidedly higher than geological evidence warrants, and a value of 400 million years may be regarded as more reasonable

While the necessary recalculations were being made in the light of the above changes, it transpired that an unsuspected constant error had entered into our earlier calculations and that the life periods arrived at were accordingly all too high The final values for the half period of the potassium isotope with mass 41 now obtained are (*a*) under the assumption that all the calcium with mass 41 was extracted, $1\ 6 \times 10^{11}$ years

(*b*) under the assumption that only one third was extracted $0\ 5 \times 10^{11}$ years

The Rhiconich and Portsoy rocks give identical figures, and the value indicated is of the order 1×10^{11} years which is in accordance with the revised results of Holmes and Lawson, *not* with the more recent work of Muhlhoff[3]

The Helmholtz Resonance Theory of Hearing

DIRECT evidence in favour of the view that the vibrating elements of the cochlea are differentially tuned for frequency has been adduced in the following way

The cochlea of the cat is exposed under Nembutal anaesthesia Viewing the preparation through a dissecting microscope, and using a dental burr, small excavations are now made in the bone, one proximal to the round window, the other towards the apex of the cochlea, the floor of these concavities may be made so thin that the cochlear fluids seep through, a state of affairs which may be easily seen through the microscope At this juncture, small beads of mercury are placed in the depressions, using a micro pipette, in this way further loss of fluid is prevented, and a good electrical contact with the fluids of the inner ear established, by the insertion of platinum electrodes into the mercury droplets

In response to sound stimuli, potentials are engendered between these electrodes and an indifferent electrode placed beneath the mylo hyoid muscle (Wever and Bray effect), and these may be recorded by means of an amplifier and oscillograph

The amplitude of the potentials in response to a note of 250 cycles has been found to be three or more times as great at the apex as at the base, while a note of 2,050 cycles gives rise to potentials of amplitude some four times greater at the base than at the apex

The Attitude of the German Government towards Science

IN spite of my letter in NATURE of February 24, there still seems to exist in English scientific circles a misunderstanding of the attitude of the new Government in Germany towards science and of the reasons why Jewish scientists have left the country May I be allowed therefore to point out the following facts ?

It must be emphasised once more that it is far from the thought of the National Socialist Government to make an attack on the freedom of scientific investigation, rather is it anxious to give scientific persons every possible help for their work I have myself on many occasions been asked by the National Socialist Ministers to join them in assisting individual scientific persons and institutes

The National Socialist Government has not subjected Jewish scientists to exceptional treatment, or forced them to emigrate it has passed a law for the reform of the Civil Service which applies to all kinds of officials, not only to those concerned with science According to this law, non Aryan officials were obliged to leave their positions if they were not appointed before 1914, or if they had not fought at the front in the War, or had not lost fathers or sons in the War No Government can be denied the right to make such rules in the interests of its own people, and no group of officials, for example, scientific ones can be made an exception to such a general law As a matter of fact however, in a number of individual cases an exception was made to the advantage of Jewish scientists

Various Jewish scientists, without being forced to do so, have given up their professorships and moved to other countries This they have done, as some of them have declared openly, out of sympathy with their Jewish kinsfolk who were affected by the law This attitude can be understood and appreciated One should not, however, set them up outside Germany as martyrs of unjust treatment by National Socialist Germany, nor quote them as signs of the denial of intellectual freedom in Germany This would be a misunderstanding of the actual position

The withholding of criticism of the new regime in Germany, or at least a conscientious regard for the truth in scientific circles will be to the advantage not only of international co operation but also of the Jewish scientists themselves

With regard to the assertions and opinions of my respected colleague, Prof A V Hill, on the above mentioned matter I should like to invite him to visit Germany and as a scientific investigator to get acquainted with the actual facts by means of his own observation and collection of evidence

Ancient Houses of North Rona

IN a short notice of a book on Ronay[1], the reviewer refers to the curious remains of dwelling houses on North Rona and likens them (from the description) to the dolmen of Locmariaquer and Carnac In the latter part of October 1928, in the course of making a census of the grey seals of Scotland during the breeding season, on behalf of the Scottish Office, W L Calderwood and I landed on this island, seldom visited by naturalists or archaeologists The salient characteristics of the houses, which seem to have been inhabited in recent historic times, are that they are half sunk in the ground, have a low wall of dry stone construction rising above the surface, which probably carried a wooden roof made water tight by turves, and were entered not directly, but through a low and generally curved, roofed passage, along which the entrant had to crawl

So far as I know, no suggestion has been made, other than the reviewer's, as to the origin of such a construction, and I write to direct attention to the possibility that they may indicate Eskimo influence or perhaps even a former Eskimo habitation of the island During excavations which revealed ancient Eskimo culture on the long since deserted island of Punuk off St Lawrence in north western Alaska Henry B Collins of the U S National Museum discovered ruined houses of the historic period which bear close resemblance to the houses of North Rona There is the same subterranean construction low walls carrying a low roof and an entrance by way of a long narrow tunnel The chief difference is in the building material for the Punuk houses are constructed of a framework of driftwood logs and the bones of whales apparently jaw bones and ribs[2]

There is no reason why North Rona lying forty miles north of the Scottish mainland might not at some early period have been colonised by Eskimos But there is the other possibility that the peculiar conditions of exposed wind swept islands lacking protective vegetation may have led to the independent development of this curious type of hut in these distant places Something of the same kind has been revealed in the excavations supervised by Prof Gordon Childe at Skara Brae in the Orkney Isles

NATURE 133 399 March 17 1934

[2] Explorations and Field work of the Smithsonian Institution in 1928 Washington 1929 p 148

Chromosome Differences in Mice Susceptible and Resistant to Cancer

COUNTS of chiasma frequency made at early mid and late diaphase of spermatogenesis have revealed a significant difference between two strains of mice one highly susceptible to spontaneous development of mammary carcinoma the other highly resistant The strains are respectively *A* and *CBA* obtained from Dr C C Little Roscoe B Jackson Memorial Laboratory Bar Harbor Maine

The mean number of chiasmata per cell is 28 44 in strain *A* and 33 12 in strain *CBA* The difference between them is 4 68 (with a standard error of 0 707) the necessary difference for P 0 01 is only 1 909 (Fisher Statistical Methods for Research Workers 3rd ed) The test for significance of the difference in distribution gave χ^2 54 93 as shown in the accompanying table the requirement for P = 0 01 is only 11 341

	Number of bivalents				
Number of chiasmata per bivalent	1	2	3	4	Total bivalents
Strain *A* (susceptible)	304	181	15	0	500
Strain *CBA* (resistant)	247	185	61	7	500
Total bivalents	551	366	76	7	1 000
χ^2 =	13 15	0 09	34 69	7 00	χ^2 = 54 93

The data have been obtained from two distinct studies in which different fixatives and slightly different methods of staining were used Twenty eight complete nuclei were analysed in the first test and twenty two in the second In each case these comprised equal numbers of nuclei at the same stages of meiosis from each strain They were from seven mice of comparable ages The results from the two studies were in complete agreement

These observations were made as a first test of a series of simple related working hypotheses on the mechanism of heritable susceptibility to cancer The hypotheses are based primarily on the somatic cell mutation theory of cancer and the discovery of genes and chromosome deficiencies affecting the mechanism of mitosis or meiosis[1] This first test of chiasma frequency is of course entirely indirect in its possible application to the cancer problem it hinges on the relationship of meiosis to mitosis[2] Though indirect the chiasma frequency test is on the hypotheses formulated of particular value since it provides a relatively precise *quantitative* measure of differences between sets of chromosomes other tests are in progress Until they are completed and other strains of mice tested for chiasma frequency it would be premature to discuss the possible significance of these data for the cancer problem They are in striking accord with expectation on the basis of the particular hypothesis they were designed to test but the possibility of an unknown factor other than cancer susceptibility being involved has not yet been eliminated

Apart altogether from the cancer problem the results obviously have general cytogenetic significance

International Status and Obligations of Science

IN NATURE of February 24 were published letters from Prof Stark and myself referring to dismissed German scholars and scientists I could not neglect the opportunity of saying that the Academic Assistance Council (Burlington House W 1) urgently needs funds Whether it was Prof Stark s eloquence or mine I am not sure (perhaps a little of each) but an unknown friend in America has written me referring to this correspondence and enclosing five cheques from members of his family to the amount of 230 dollars to be used for furthering this assistance He hopes to send a little more

His generous action will provide for one of our colleagues for several months but—will Prof Stark allow me to say ?—many still need help and there is next year and the year after before a limit to the problem can be seen and who can tell what may happen elsewhere ? This gift represents 0 2 per cent of what is still required for the next two years Will other readers of NATURE help with the remainder ?

Bronze Age Cephalotaphy in Wiltshire. Mr J F S Stone records in *Man* for March the discovery of a separate burial of a skull in the course of excavations of Beaker Folk dwelling pits surrounding the cluster of flint mine shafts on Easton Downs, Wilts Authenticated instances of the ancient burial rite of cephalotaphy are rare in England The barrow in which the discovery was made is small and low, being 23 ft in diameter and 2 ft high The body of the barrow was composed entirely of chalk rubble which had been extracted from the surrounding ditch The ditch was square in section, 2 ft 3 in wide and cut in the chalk to a depth of 16 in A shell filled band of humus containing numbers of well patinated flints to a depth of 8 inches overlay the primary chalk silting Very slightly north of central was found a comparatively large stone cist, 5 ft 6 in long, by 3 ft 2 in wide, cut into the chalk twelve inches below the original surface The total depth was 3 ft 8 in In the south west corner was an almost perfect skull, twelve inches from the west wall and seven from the south It lay on the left parietal and faced south, the skull base, therefore, being toward the west wall and thus precluding the possibility of any body having been attached to it at the time of burial The skull had been pillowed on six inches of chalk dust The atlas and axis were articulated in their normal position, but the lower jaw had been moved by rabbits to a distance two feet away The vertebræ fell away on the skull being removed, proving that it had not been moved since the flesh rotted away Propped against the vault of the skull, and erect on its broader end, was a roughly chipped bar of flint 9½ in long, 3½ in wide at the broader end, and averaging 2 in thick No dateable object was found, but various considerations suggest the Early Bronze Age Miss M L Tildesley reports on the skull, her conclusion being 'Early Bronze Age very probable, La Tène or Romano British possible, Anglo Saxon improbable"

Clan and Moiety Mr Ronald L Olson has made a study of the derivation of social organisations among the American Indians, which is published under the title Clan and Moiety in Native America" (*Univ California Pub Amer Archæol and Ethnol*, vol 33, No 4) Except among the Eskimo and in Patagonia, clans and moieties are found in every culture area in the two Americas In all those, except on the north west coast and in the California Great Basin, both maternal and paternal descent occur, while the dual grouping and the multiple type are also found, sometimes singly, sometimes co existing Probably three fourths of the area of the Americas was occupied by tribes organised into unilateral social groups It is believed that a sufficient number of extrinsic, arbitrary factors are shown to underlie these institutions in their several areas to support the view of the unitary origin of native American unilateral groupings, contrary to the current opinion of American anthropologists, who hold that they represent from two to upwards of six independent growths If the hypothesis of the unity of origin of all the unilateral institutions of native America be accepted, their wide spread distribution points to a very respectable antiquity The clan organisation bulks large in every area from which we have data, except in the southern part of the North Pacific coast Unilateral institutions may be assigned to the 'archaic' period of American culture along with shamanism, crisis ceremonies, and so on, while the derivation of American clans from the Old World as a concomitant of the migrations makes it unnecessary to posit their special creation in the New World The Old World distribution of unilateral institutions falls into line, being practically universal in Siberia, except among some of the Palæo Siberians There is the strongest evidence for them in Old China and for their antiquity over the greater part of the Old World

Maximum Yield of Ceylon Pearl Oysters In the September number of the *Ceylon Journal of Science* (Section C Fisheries Vol 4 1933) there are two very interesting papers connected with pearl oysters, "The Maximum Pearl Yield of a Pearl Oyster Bed" by Joseph Pearson, and "Further Observations on the Age and Growth rate of the Ceylon Pearl Oyster, *Margaritifera vulgaris*, with Special Reference to Oysters of Donnan's Muttuvarattu Paar" by A H. Malpas The first discusses the theoretical aspects of the problem of deciding the optimum for fishing a mixed bed of pearl oysters In the second, some practical aspects of the same problem are indicated and an account is given of the different phases in the life history of a bed of oysters on one important paar Dr Pearson deals with his subject on mathematical principles, basing his work on the two main considerations affecting the problem (1) that the normal rate of mortality of an oyster bed is very high, and (2) that the pearl yield of the oyster increases with age Oysters older than 5 years are very rare, and the best age for fishing is probably between 3½ and 4 years Having due regard for the age limit of the oyster, the longer the fishery is postponed the fewer the oysters but the greater the average pearl yield The question is how to strike the balance and find the time when the bed may be expected to attain its greatest value At present, purely practical methods are used for estimating the numbers and computing the approximate pearl value of a bed, but the author suggests that a valuable research could be followed in the immediate future on the lines laid down in his paper for determining the optimum of a bed of mixed oysters

Plankton in the Java Sea. Dr H C Delsman in his paper "Over het Productievermogen der Tropische Zeeën' (Delsman en Hardenberg De Indische Zeevisschen en Zeevisscherij ter perse bij Visser and Co, Batavia C 1933) deals with quantitative plankton investigations in the Java Sea and phosphate determinations As was to be expected in a shallow tropical sea, he finds much less plankton in these regions than in the North Sea, where he has made similar observations at the *Haaks* Lightship The phytoplankton is restricted to a relatively narrow belt along the coast, the life farther out being predominantly animal In Sunda Strait, which has strong tidal currents, there was much more plankton, especially on and near the border of the continental flat Copepods were more than five times as numerous as in the Java Sea Five large species of copepods are predominant in the plankton—*Euchaeta concinna*, *Undinula (Calanus) vulgaris* forma *minor*, *Eucalanus subcrassus*, *Candacea bradyi* and *Labidocera acuta*, the largest being *Undinula*. There are also many smaller species The diatoms are mostly well known and widely distributed species which occur also in northern seas The copepods are very important as they are the chief fish food. It is interesting to find that the structure of the gill rakers is finer in those plankton-eating fishes which feed on the fine coastal plankton than in those which feed on the larger plankton farther out

Deposition of Fat in the Animal Body The mechanism of the penetration of fat into the cells of adipose tissue during fattening and its issue from the cells during fasting is a physiological problem which, despite much investigation, still remains unsolved In a paper published in the *Memoirs of the Royal Italian Academy*, 4, 1933, Dr Gaetano Quagliariello summarises the present state of knowledge of this question and gives a brief account of his own experiments His results indicate the existence, in the cells of adipose tissue, of a lipase capable of attacking glycerides of the higher fatty acids and of an enzyme which is able to dehydrogenate the higher fatty acids but not their esters It was found, moreover, that lipolysis and also oxidation phenomena which must be, at least partly, dehydrogenating in character, are detectable in adipose tissue detached from the organism In experiments on dogs it was observed that, during fasting the degree of unsaturation of the fatty acids, both of the adipose tissue and of the blood, underwent appreciable increase On these data is based the hypothesis that, prior to its mobilisation, fat is hydrolysed and the resulting fatty acids are rendered sufficiently unsaturated to make them diffusible It is considered probable also that, under normal conditions of nutrition at any rate, penetration of fat into adipose cells is effected by a similar mechanism

Action of Growth Substance in Plants It has long been recognised that the terminal bud of a stem inhibits the development of lateral buds, causing them to remain dormant, but the mechanism of this action has not been understood Messrs Thimann and Skoog (*Proc Roy Soc*, B, 114, 317) put forward an interesting hypothesis based on numerous experiments with young plants of *Vicia Faba* The work of Went and others has shown that the coleoptile of *Avena* produces a growth substance (auxin) The present authors conclude that the same substance, diffusing from the terminal bud, acts as an inhibitor of growth in the buds below By placing the terminal bud on a small block of agar into which the auxin diffused, and then placing the agar block on an *Avena* coleoptile, they were able to get a measure of the amount of growth substance produced by the terminal bud It was also found that the lateral buds produce no auxin while dormant, but begin to produce it when their growth begins The growth substance was also produced by the leaves, especially when young Application of growth substance to a decapitated stem similarly suppresses the development of the lateral buds in accordance with the amount applied It was further shown that the growth substance causes elongation of the stem, both in intact plants and in isolated portions of stem, the stimulus being to cell elongation and not to cell division The amount necessary to produce elongation is much less than that required for bud inhibition The stem was found to show a greater response to auxin in the dark, but the production of this substance takes place only in the light It thus appears that the same substance which promotes cell elongation in the stem inhibits the development of lateral buds

✓**Leaf Stripe of Oats.** A severe disease of oats known as leaf stripe is caused by the fungus *Helminthosporium avenæ*. It can be controlled readily by means of disinfectant dusts applied to the grain, but several new facts about the life history of the fungus are published in a recent paper ("Studies in the Morphology and Biology of *Helminthosporium avenæ*", by R W G Dennis, *Trans Brit Mycol Soc*, 18, part 3, 223–237, Dec 1933) Primary symptoms occur on the seedlings, the coleoptile being infected from spores on the grain each year Then spores are produced, which infect the more mature parts of the plant, giving secondary symptoms The fungus produces sclerotia and spores within pycnidia, and grows best at a temperature of 20° C Secondary infection is largely dependent on a high relative humidity in the crop The paper under review is the result of fifteen years' investigation of the causal fungus

Propagation of Plum Rootstocks The necessity for the vegetative propagation of rootstocks for fruit trees is now generally realised, and has stimulated the investigation of various methods of multiplication Layering and stem cuttings are used in Great Britain, though on the Continent root cuttings are employed to some extent A great deal of information is given in a recent paper by Messrs T N Hoblyn and R C Palmer (*J Pom and Hort Sci*, 12, No 1, March 1934) The variety Pershore Egg proved entirely unsuitable for propagation by root cuttings, whilst the Common Mussel plum rooted with ease October, December, January and February seem to be good months for the preparation and planting of cuttings, which are recommended to be 9 in long, and not less than ½ in in diameter The yield of cuttings from even a 3 year old tree is low, and the method would seem to be applicable commercially only when roots can be trimmed from general nursery stock Great interest is attached to the method of experiment, which departs from the usual plan of controlling the variables, and combines them in a complete variety of ways, thus giving combinations some of which are successful

✓ **Sodium Chlorate as a Weed-Killer** Dr M A H Tincker has prepared a useful digest of our present knowledge of sodium chlorate as a weed killer ("Tests of Sodium Chlorate as a Garden Weed Killer", *J Roy Hort Soc* 59, 107, Feb 1934) The paper begins with an account of experiments conducted at the Society's gardens at Wisley on the destructive action of sodium chlorate on various weeds It is shown that it is quite effective, and it ceases to have any action after about seven months from the time of application There are thus no harmful after-effects as with arsenical weed killers From other literature, it appears that a 10 per cent solution (1 lb per gallon of water) is required for the eradication of large grasses and docks, a 5 per cent solution for herbaceous weeds and small grasses, whilst small annual weeds are destroyed by a 2½ per cent solution The liquid is applied at the rate of 1 gallon per 10 square yards Dry sodium chlorate must be handled with care, but the chances of any grazing animal taking a harmful dose seem very remote Costs of treatment are low, and one may imagine a time when a dressing of sodium chlorate may replace the exorbitant incubus of a bare summer fallow

Temperature of the Atmosphere in Northern India. In *Gerlands Beiträge zur Geophysik*, 39, 121, 1933, there is a paper by Barkat Ali of the Meteorological Office, Poona, entitled 'High Lapse Rates of Temperature and their Diurnal Variation in the Surface Layers of the Atmosphere over Northern India" The observations were made at Agra (lat 27° N) in March 1925 with sounding balloons carrying a temperature recording apparatus of greater sensitivity than those usually used in work with sounding balloons, and protected from solar radiation by a polished aluminium shield They showed a surprisingly rapid decrease in the amplitude of the diurnal variation of temperature with height, the change being from an average of about 25° C near the surface to about 2° C between heights of 300 and 400 metres above the surface The relationship between the amplitude of the diurnal range and the height was such as to suggest that the amplitude would probably be negligible at a height of 1,000 metres at Agra The lapse rate of temperature was generally greater than the dry adiabatic rate (9 9° C per 1 000 metres) near the surface during the middle of the day and at times even exceeded the lapse rate corresponding with a constant air density in the vertical (34 2° C per 1,000 metres) These inversions of temperature generally extended to a height of 300 or 400 metres, and occasionally temperature was 16° C higher at the top of the inversion than 1 2 metres above the ground, though generally the difference was between 4° C and 6° C

Secondary γ-Rays of Nuclear Origin. Gray and Tarrant Chao, and other workers have found a secondary γ radiation when several elements are exposed to the penetrating γ rays from thorium C'' Gray and Tarrant have now examined this radiation in more detail (*Proc Roy Soc*, A, Feb) The absorption curve of the radiation in lead has been very carefully determined, using alternative primary sources of radium C and thorium C All the elements studied give a soft secondary radiation of quantum energy about 0 5 × 10^6 volts when irradiated by thorium C'' With lead (and to a lesser extent with elements of lower atomic number), a harder radiation of energy about 1 1 × 10^6 volts is also emitted When radium C rays were used, a similar phenomenon was observed, but the soft radiation had an energy which the authors think is significantly less than 0 5 × 10^6 volts This is extremely puzzling, since this difference seems to exclude the possibility that the radiation is a characteristic radiation of the secondary emitter and that the primary radiation serves simply to excite it Special experiments with a Wilson chamber and with a hydrogen filled ionisation chamber showed that the radiation was really γ rays and not a neutron emission The emission seems to be isotropic and to correspond with the whole of the 'anomalous' nuclear absorption of γ rays The authors examine the question of the relation of the radiation to the production and annihilation of positive electrons—an explanation on these lines is very attractive for the thorium rays but seems to leave the phenomena with radium rays unexplained

A New Diode for Electronic Oscillations. Reference was made in a letter to NATURE of May 13, 1933, p 691, to the construction of a novel and simple type of two-electrode valve for the generation of very high frequency electronic oscillators The same contributor, Mr J S McPetrie, has now published in the *Wireless Engineer* of March 1934 further details of this diode and some experiments carried out with it at the National Physical Laboratory The valve differs from the conventional type in that the central electrode is the anode, consisting of a tungsten rod 1 mm in diameter, around which as axis four tungsten filaments are arranged on a ring 12 5 mm in diameter When these filaments are heated and the anode potential is raised to about 360 volts, oscillations are obtained either in an aerial connected to the anode or in a Lecher wire system suitably connected between anode and filament These oscillations are presumed to arise from the periodic motion of the electrons past the anode, along diameters of the cylindrical cathode which the four filaments virtually comprise The wave length of the oscillations under the above conditions was about 1 5 metres and was mainly dependent upon the adjustments of the external circuit With an anode potential of 600 volts, the wave length could be varied from 0 94 metre to 1 2 metres by adjusting the length of the circuit The intensity of the oscillations obtained passes through a maximum value as the filament current is varied, but their production was shown to be independent of the application of an external electrostatic or magnetic field to the valve

Action of Papain on Ovalbumin. Svedberg and Eriksson (*J Amer Chem Soc*, 56, 409, 1934) have made a number of determinations by the ultra-centrifuge method of the sedimentation constant and molecular weight of products obtained by digesting pure crystalline ovalbumin with activated and unactivated papain at 40° Attempts were made to separate the products by fractional dialysis and fractional precipitation with ammonium sulphate, the fractions being ultra-centrifuged Unactivated papain produced no influence on the sedimentation constant of ovalbumin and no non centrifugible products were formed Activated papain gave rise to three kinds of disintegration products One was a non centrifugible substance which probably contained lower polypeptides and aminoacids The second was a centrifugible substance of a sedimentation constant of about 0 6 × 10^{-13}, which with regard to molecular weight is of the same order as the protomines The third product had the same molecular weight as ovalbumin, with a sedimentation constant of 2 7 × 10^{-13}, and was probably formed by the loosening of some of the bonds within the ovalbumin molecule, thus causing it to assume a highly dissymmetrical shape This may represent the first step towards the breaking up of the molecule into individual parts The third substance was found to be practically homogeneous with regard to molecular weight Papain has its maximum activity within the stability range near the isoelectric point of the protein

Superheated Water Mr J Small, of the James Watt Engineering Laboratories, University of Glasgow, has sent us an account of an experiment in which a drop of de aerated water was heated in a glass tube of 1/16 in bore open at one end The temperature of the oil bath in which the tube was heated was taken to 304° F before the drop was explosively expelled The degree of superheat was 90° F, whilst previous experimenters, it is stated, attained only 16° F. of superheat

Conservation of Tropical Forests

THREE articles which have appeared in the *Empire Forestry Journal* (vol 12, No 1, 1933) display the difficulties which exist in conserving and putting to their fullest utilisation the tropical forests of the Empire To take the second case first, Sir Ralph Pearson, formerly director of the Forest Products Laboratory at Princes Risborough discusses the problem of creating and developing markets for Empire hardwood timbers at home

Sir Ralph briefly reviews the reasons why well known timbers have not found favour amongst markets in Great Britain, ascribing some of the causes to the fact that the consignments sent over were often not carefully chosen, nor, with the facilities available in the forests, was there much chance of their being so chosen when the short handed and over worked forest officer was himself responsible for their dispatch Sir Ralph deprecates trying to push too many new timbers upon the markets at the same time, and points out the way in which chosen timbers should be forwarded and tested

A second article, by Mr J B Clements, conservator of forests in Nyasaland, treats of the cultivation of finger millet (*Eleusine coracana*) and its relation to shifting cultivation in Nyasaland This article, and the practice dealt with, is typical of one of the chief sources of the disappearance of valuable forests in tropical countries, the difficulties facing the administration, not always convinced of the increasing injury supervening, in weaning the people from so wasteful a form of primitive agriculture, and finally, of the troubles of a forestry department well aware of the evils resulting from the practice

'It is therefore clear that shifting cultivation in Nyasaland is accelerated to a very considerable extent by the growing of *Eleusine coracana* under prevalent methods Compared with the growing of other crops, the requisites of the millet make extravagant demands as regards the use of land, and systematic burning of the top soil combined with flat cultivation when carried out on any large scale leads to widespread loss and impoverishment of the soil, particularly in hilly country Rapid deforestation inevitably takes place in any wooded country where the millet is grown, as conditions are there ideal for providing both new soil for each crop and fuel for heating the soil "

The third article, by N V Brasnett, conservator of forests, Uganda, discusses the formation of State forests, and forest rights and privileges of local inhabitants in Uganda After briefly reviewing the position of the colony from the day, in 1890, when Capt (now Lord) Lugard signed a treaty on behalf of the British East Africa Co with the King of Buganda the declaration of the British protectorate in 1894, and Sir Harry Johnston's arrival in 1899 and subsequent organisation of the administration of the country, the author concentrates upon the various arrangements, regulations and ordinances for the management of the forest areas of the country

It is impossible to deal with the varying policies to which succeeding administrations subjected the forests after the first and promising lines were laid down But a perusal furnishes evidence that one of the past flaws in colonial administration has been the refusal or inability of those responsible for the future welfare of their charges to lay down a definite forest policy, based on wide views, and to adhere to it

Mr Brasnett ends his summary of the present position of the forests in Uganda with the sentence

When formation is completed it is estimated that the State forests of Uganda will constitute just about 2% of the total land area of the Protectorate, and the total forest area, including private woodlands and the valuable savannah, just over 3%, so that it is obviously essential to preserve the whole of this small percentage " Many conversant with the tropical forest and the importance it plays in countries where it exists would consider the percentage dangerously low

Band Spectrum of PN and its Significance

OF the diatomic emitters of band spectra, few have been more extensively studied than the 14 electron molecules N_2 and CO, which are responsible for many observed band systems and, unlike most emitters, are well known as stable molecules rather than as intermediate products in chemical reactions or equilibrium products at high temperatures Emitters which are chemically or spectroscopically analogous to these two have, as would be expected, also received considerable attention, the best known examples being the 30 electron molecule P_2 and the 22-electron molecules SiO and CS

To the latter category the PN molecule becomes an interesting addition as the result of the recent discovery and analysis, by J Curry, L Herzberg and G Herzberg[1], of an ultra violet band system which is produced by an electrical discharge through a mixture of phosphorus vapour and pure nitrogen With a heavy discharge (about 6000 v and ½ amp) in a water cooled tube, this PN system has been photographed in the first and second orders of a 3 m grating, and both the vibrational and rotational structures analysed

The new bands extend from λ2375 to λ2992, are degraded towards the red and have a fine structure characteristic of the electronic transition designated as $^1\Pi \rightarrow {}^1\Sigma$ The system is therefore similar to those of the iso-electronic molecules CS and SiO in the same spectral region and to the well known fourth position system of CO and the Lyman system of N_2 [2] The P_2 ultra violet system is not analogous to these as it is due to a $^1\Sigma \rightarrow {}^1\Sigma$ transition[3], other and less refrangible P_2 bands are known, some of which may, when analysed, prove to belong to the expected $^1\Pi \rightarrow {}^1\Sigma$ system

From the accompanying table of the more important numerical constants for the electronic states concerned, it is clear that the three 22 electron molecules are similar to one another and intermediate to the 14 electron and the 30-electron molecules in respect of the vibrational coefficients ω_e and $x_e\omega_e$, the rotational coefficient B_e and the equilibrium inter-nuclear distance r_e With CO, N_2, SiO and P_2, the band systems under discussion have been observed in absorption as well as in emission, and the lower ($^1\Sigma$) states are therefore stable ground states The same is expected, though not yet observed, to be true of CS and PN, that is to say each of these should be capable of existence as gaseous substances in the absence of an electric discharge, J Curry and L and G Herzberg are further investigating the PN system from this point of view

Molecule	$^1\Pi \rightarrow {}^1\Sigma$ ν_0 (0 0) cm.$^{-1}$	Upper State $^1\Pi$ ω_e cm^{-1}	$x_e\omega_e$ cm^{-1}	B_0 cm^{-1}	r A U	Lower State $^1\Sigma$ ω_e cm^{-1}	$x_e\omega_e$ cm.$^{-1}$	B_e cm^{-1}	r_e A U
(14) CO	64765	1516 7	17 24	1 600	1 232	2167 4	12 70	1 85	(1 15)
(14) N_2	68962 7	1692 28	13 318	(1 52)	(1 26)	2359 60	14 445	1 992	1 094
(22) SiO	42690 0	851 51	6 143	0 6270	1 62	1242 03	6 047	0 7238	1 51
(22) CS	38796 3	1072 2	10 05	0 74	1 61	1282 5	6 00	0 79	1 56
(22) PN	39688 5	1103 09	7 222	0 7274	1 542	1337 24	6 983	0 7834	1 487
(30) P_2						780 43	2 812	0 3133	1 856

The heat of dissociation of the $^1\Sigma$ state of PN is estimated as 7 8 volts from a Birge Sponer linear extrapolation of vibrational energies and as 6 3 volts from a consideration of probable products of dissociation It is thus somewhat less than that of N_2 (recently given as about 7 9 volts[4] rather than the hitherto accepted value of about 9 0 volts[3]) and greater than that of P_2 (5 0 volts[3]) Similarly the heats of dissociation of CS and SiO (each roughly 8 volts) are less than that of CO (about 10 volts)

The molecules discussed here are all composed of nitrogen, phosphorus and their immediate neighbours in the periodic table From the atoms preceding and following these we have other 22 electron molecules about which, however, nothing can yet be stated, namely BCl (bands observed in the same spectral region but not systematised[5]) and AlF (expected band system not yet recorded)

Biology of Heavy Water

IN *Science* of February 16 1934 Prof Gilbert N Lewis summarises the results of certain sporadic attempts to observe the effect of water containing heavy hydrogen, H^2, upon living organisms Experiments have necessarily been confined to small organisms, though some preliminary observations on mice are included The first experiments were upon tobacco seeds, the germination of which was completely retarded by pure H^2_2O and slowed up some 50 per cent by water containing 50 per cent H^2_2O Seeds transferred to normal water after three weeks in pure H^2_2O sprouted in about half the cases but gave unhealthy seedlings Yeast cultures in an appropriate nutrient medium dissolved in pure heavy water failed to grow, and Pacsu has also shown that the evolution of carbon dioxide by yeast from sugar solution made up with heavy water is much diminished

In an experiment that was expensive if preparatory in nature, a mouse was supplied in three doses with some 0 66 gm of pure H^2_2O The mouse survived, though during the experiment it showed marked signs of intoxication" The symptoms of distress seemed more marked after each dose but not cumulative, which led Prof Lewis to conclude that the heavy water was being voided, but no preparation had been made to test this point Prof Lewis concludes that H^2 is not toxic in any high degree but that its complete substitution for H^1 leads probably to a complete inhibition of growth, an effect which is to be traced to the greatly reduced rate of all physico chemical processes when H^2 is substituted for H^1 '

Mr S L Meyer of the Vanderbilt University Biology Department describes in *Science* of March 2 culture experiments with a blue mould, in which those grown on media made up with one out of every 214 hydrogen atoms H^2 gave sixteen times the yield of fungus as those grown on control solutions free from H^2

The late Dr Edward W Washburn and Dr Edgar R Smith have been carrying on experiments at the Bureau of Standards at Washington in which they have studied the proportion of H^2 atoms present in the tissues after plants have grown in normal soil solutions So far as could be judged, rooted willow cuttings absorbed H^1 and H^2 in the proportions in which they were present in the original water supply, but apparently the heavy hydrogen was selectively accumulated in the tissues as the expressed sap contained water 2 8 parts per million heavier than normal water whilst the water obtained from the destructive distillation of the willows was 5 4 parts per million heavier than the normal supply Dr Washburn died suddenly on February 6, his report with Dr Smith has been published since, in *Science* of February 23

Universe and Atom

THE issue of *Die Naturwissenschaften* of March 9 contains the address on this subject which Prof Wehl of Göttingen gave at the opening of the holiday course on mathematical sciences given at Göttingen in July 1933 His object was to put before his audience only such conclusions as are at the present time reasonably certain and to avoid any fantastic speculations

By representing space in the space time continuum as the abscissa and time as the ordinate of a point on a curved surface, Prof Wehl shows how the Einstein continuum with its mass distribution is represented by a cylindrical surface with its axis vertical and its radius determined by the density of distribution of mass Stars at rest are represented by generating lines and the movement of light through the universe by spirals the pitch of which is equal to the time the light takes to go round the universe The stars are thus represented at different epochs separated by æons

De Sitter's massless continuum is, on the other hand, represented by a hyperboloid of one sheet with its time axis vertical, and lines of shortest length now represent the stars while the movement of light through the universe is represented by a straight line generator in which a tangent plane to the asymptotic cone cuts the surface As this cannot intersect a geodesic a second time, there is no repetition of the representation, and as the geodesics themselves change their distances apart as they travel over the surface the universe must be either expanding or contracting

Neither the gravitational universe of Einstein nor the non gravitational one of De Sitter corresponds sufficiently closely with the facts, but the later one of Friedman and Lemaître, according to which space is spherically bounded and the boundary expands with time, is much more satisfactory The radius of space is about 10^{27} cm and the total mass it contains is about 10^{27} that of the earth, possibly due to 10^{80} particles

In the atom the electrical forces between its constituents are about 10^{40} times the gravitational, a ratio which may have some connexion with the square root of the number of particles in the universe The wave length associated in wave mechanics with the electron, when multiplied by the constant known as the fine structure constant (1/137), gives the radius of the electron and when divided by it the radius of the atom The product of the wave length of the electron wave by the square root of the number of particles gives the radius of the universe and when divided by it the gravitational radius of the electron

Although in this theory the appearance of the square root of the number of particles in the universe can be understood, there still remains considerable obscurity with regard to the wave length of the electron wave and the fine structure constant

Science News a Century Ago

John Phillips at King's College

When Lyell in 1833 resigned the chair of geology at King's College, London, he was succeeded by John Phillips (1800–74), the nephew of William Smith Phillips began his courses of lectures on April 21, 1834 The science of geology, he said, was of but recent growth and it was necessary that students should be cautious as to the reception of theories, many of the theories which had been introduced were the results of imagination rather than the deduction of actual observation Nothing was to be received as truth but what was warranted by actual observation and diligent research If the science were pursued with strict attention to these preliminary principles, the benefits which would arise to those who pursued it would be commensurate with their desire of truth In the course of his remarks, he described the primary, secondary and tertiary deposits and explained the position of the various strata of rock He directed attention to the incontrovertible fact that in the various strata fossils had been discovered including many thousands of species of animals and vegetables which were no longer found in the animal and vegetable kingdoms by which the surface of the earth was covered, and deduced from this fact that it was obvious that the system of Nature had in the revolution of ages under gone many changes He reminded the students of the high eminence to which their fellow countrymen had exalted the science and begged them to remember that the philosophers of the Continent had their eyes upon their proceedings and success

Honours for Men of Science

Shortly after the first meeting of the British Association, William IV conferred the Guelphic order of knighthood upon David Brewster, Charles Bell, John Leslie, John Herschel and other men of science In the spring of 1834, the subject of honorary distinctions for eminent scientific persons was discussed in the House of Commons, the discussion leading Vindex' on April 22, 1834, to address a letter to the editor of the *Times* mentioning one or two points which he considered had been over looked In the first place, he said, the Guelphic order of Hanover, the only one conferred so far, was one of the lowest on the Continent The title of knight could not be assumed until the recipient had been to court, and as this could not be done under an expense of nearly £200, several persons whom it had been intended should be honoured had been unable to stand this expenditure Secondly, the order was a foreign' one and after the death of King William it could not again be granted and the knighthoods already conferred would lapse It surely," said Vindex, would be more becoming in the Sovereign and more worthy of the nation either to make a new order or enlarge one of the present ones so as to embrace such persons as are distinguished in art or science "

Progress in Lighthouse Illumination

In the *Mechanics Magazine* of April 26, 1834, a correspondent described a visit he had made to the National Gallery in Adelaide Street, London, where an exhibition was being held illustrating the various methods of illumination in use for lighthouses and for geodetical operations So late as 1811, the writer said, the Eddystone lighthouse was illuminated by wax candles, while in 1812 a coal fire was still in use at the Lizard By 1834 the general method adopted in British lighthouses included the use of oil burning Argand lamps in conjunction with parabolic mirrors of silvered-copper This type of illumination was stated to be due to Mr Ezekial Walker of Lynn, who had fitted up the Hunston light on the Norfolk coast in 1778 Many kinds of vegetable and animal oils had been tried with Argand lamps but spermaceti had been found to be the most suitable Coal gas had been tried in some foreign lighthouses, that at Dantzig having been lit by gas in 1819

After referring to the introduction by Arago and Fresnel of the plano convex lens in French lighthouses and to the Cordovan lighthouse at the mouth of the Garonne, then the finest in the world, the writer said that, as lenses of more than 15 inches diameter were not easily made, the lens system would not have found the favour it had but for "the discovery of our distinguished countryman Sir David Brewster that by surrounding any lens with a series of glass rings of a particular curve, it might have its effect magnified to any given extent" Other methods of illumination shown included a primitive form of arc light and the hydro oxygen limelight of Lieut Drummond, which gave a light ' only inferior to the sun itself"

Botanic Garden, Oxford

'It is much to be regretted that the city of Oxford has not a botanic garden suited to the rank which it holds as a British university Were a small sum contributed by each of the colleges yearly, even the present garden might be rendered doubly efficient more especially if the adjoining ground at present occupied by Mr Penson, were added to it, and a part, or the whole of the meadows of Christ Church But the situation is altogether bad, and, for a botanic garden worthy of Oxford, a dry, open, ample, airy piece of ground should be selected outside of the town, say, somewhere about Jeffery s Nursery The present botanic garden might still be continued as such, on a smaller scale, so as to suit the income destined for its support Till lately there has been a great want of botanical taste among the Oxford professors, but hope that a taste for botany, as well as a taste for geology, is now dawning upon them, and, whenever it does, they will soon produce a botanic garden worthy of themselves After a botanic garden is established, a zoological garden will follow, and, perhaps, ultimately, a public ornamental garden surrounding the whole city as a breathing zone' (J C Loudon, *Gardener's Magazine*, April 1834)

Societies and Academies

London

Physical Society, March 2 A O Rankine A simple method of demonstrating the paramagnetism and diamagnetism of substances in magnetic fields of low intensity (see Nature, 133, 150, Jan 27, 1934) A M Ferasah Anomalous changes in temperature due to thermionic emission in the filaments of valves In some valves the steady filament temperature is lower when the anode is positive, as would be expected but in other valves it is higher This anomalous increase in temperature is due to radiation from the anode and is larger for valves which have a high anode dissipation and an anode which closely surrounds the filament After correction for this effect has been applied, the work function can be approximately calculated from measurements made on an ordinary valve T Smith Change of variables in Laplace's and other second order differential equations Transformations of variables are expressed as matrix products, the effect of transposition being particularly considered, and the results are applied to the transformation of the general second order differential expression Mary Taylor The Appleton Hartree formula and dispersion curves for the propagation of electromagnetic waves through an ionised medium in the presence of an external magnetic field (2) Curves with collisional friction Four typical frequencies have been chosen for the calculations, one from each of the classes into which the frequencies fall when collisional friction is absent, as described in part 1 The corresponding wave lengths are 80, 240, 400 and 1,000 metres The various stages in the effect of increasing collisional friction have been found to be usefully represented by collisional frequencies of 10^5, 10^6, 10^7 c/sec and curves are given showing the indices of refraction κ_r $(r=a, b)$, and the real part and imaginary part of M_r^2 or $(\mu_r - i\kappa_r\, c/p)^2$, together with the polarisations of the basic modes as functions of the electronic density for each of the four frequencies and collision frequencies named The process of evaluation of M_r and of the polarisation is described The attenuation and absorption are found to be, in general, greater for the right handed component than for the left-handed component, with the direction of magnetic field appropriate for down-coming waves in the northern hemisphere The use of the dispersion curves in the interpretation of propagation phenomena is discussed J McGarva Bruckshaw An instrument for electrical prospecting by the inductive method In the Bieler Watson method of geophysical surveying, in general, the horizontal field is not in quadrature with the vertical field An instrument has been designed which will allow the horizontal field to be compared completely with the vertical field, an important feature being that the horizontal components in phase and in quadrature with the vertical field are obtained directly from the instrument readings The apparatus has been tested on elliptically polarised fields and has given satisfactory results

Paris

Academy of Sciences, February 26 (*C R*, 198, 777–860) C Matignon and A de Passillé The ammonium arsenates An account of the preparation of anhydrous triammonium arsenate, of the dissociation of this and the diammonium arsenate The properties of a new ammonium metarsenate are also described Marin Molliard and Robert Echevin The ovarian fluid of rust (*Agrostemma Githago*) and its relations with the seminal tegument R de Montessus de Ballore The determination of the median in the binomial function Paul Lévy The generalisation of the differential space of N Wiener René Lagrange A class of congruences of circles S K Zaremba The course of the integral curves of the equation $Y(x\ y)dx - X(x,y)dy = 0$ in the neighbourhood of an isolated singular point A Kovanko The structure of almost periodic generalised functions Jean Grégoire Certain shock phenomena produced in differentials R Swyngedauw The friction couple of ball bearings Loève The integration of Dirac's equations Y Rocard The quantic absorption of sound in gases Arcadius Piekara and Bruno Piekara The thermal hysteresis of the specific inductive capacity and of the conductivity of aqueous solutions of gelatine J Thibaud and F Dupré la Tour The diffusion and absorption of positive electrons traversing matter Experiments based on photographic methods, using the Chalenge Lambert recording microphotometer, lead to the conclusion that positive electrons behave like negative electrons, they undergo multiple diffusions near the charged atomic centres with progressive deceleration G A Boutry and J Orcel Remarks on the comparison of the properties of vacuum (photoelectric) cells with those containing a gaseous atmosphere Criticism of work on the same subject by L Capdecomme Alb Perrier and Mlle T Kousmine The longitudinal magneto thermoelectric effects in nickel and iron The experimental laws From experiments with an iron nickel couple it is concluded that, with the magnetisation parallel to the temperature gradient, the thermoelectric power is increased normal magnetisation, on the contrary, lowers it O Miller and J Lecomte The infra red absorption spectra of the stereoisomeric orthodimethyl-cyclohexanes Since the molecular structure of these two stereoisomers is not the same, different infra red absorption spectra would be expected, and this is shown by experiment to be the case The Raman spectra of the same compounds are also given A KASTLER The amount of polarisation of the fluorescence of mercury vapour in the presence of nitrogen JEAN GENARD The magnetic extinction of the fluorescence of the diatomic molecules of tellurium Repetition of the work of Smoluchowski, utilising the large Bellevue electromagnet, which gives stronger fields MME BRANCA EDMÉE MARQUES The distribution of the radium in crystals of radiferous barium bromide EDMOND BANDERET The formation of Liesegang rings by electrolysis Utilising the method of producing very clear rings described in an earlier note Veil s relation $\sqrt{\delta}=an+b$, where n is the order of ring and δ the distances between the rings was verified, a was also found to be inversely proportional to the voltage applied MLLE LUCIA DE BROUCKERE The adsorption of electrolytes by crystalline surfaces The influence of the sign of the electric charge of the adsorbant A MICHEL LÉVY and H MURAOUR The possibility of utilising the microscope in the study of the phenomena of detonation Results obtained by detonation of lead azide, in quantities of the order of 0 5 mgm, and subsequent examination of the lead deposits under the microscope P JOB The constitution of hydrobromic solutions of salts of copper and cobalt A TRAVERS and PIERRE LEDUC A reaction differentiating various hydrated calcium aluminates P BASTIEN The existence of three allotropic varieties of calcium Differential thermal analysis, differential thermoelectric power, expansion and hardness all indicate allotropic changes at 260° C and about 430° C, thus proving the existence of three allotropic varieties of calcium M CHÂTELET and MME P M CHÂTELET Some reactions of divalent chromium acetate Descriptions of the preparation of dry chromous acetate and its reactions with dry hydrogen chloride, pyridine and ammonia MAURICE LOURY An acid alcohol containing the acetylene linkage phenyl phenyl ethinylglycollic acid, $C_{16}H_{12}O_3$ MARCEL GODCHOT and MAX MOUSSERON The resolution of 1 2 trans-cycloheptanediol into its optical antipodes MME E JÉRÉMINE Some rocks from Kenya Colony J CHAZE The mode of formation of the aleurone grains in the Gramineæ and the production in the latter of oxyflavonic and anthocyanic compounds RENÉ VANDENDRIES The haploid and diploid conidian cycle in the Basidiomycetes R KÜHNER The utilisation of cresyl blue in systematic mycology G GUITTONNEAU and A LEROY Opotherapic feeding in milch cows The system of feeding suggested by G Monnot has been tested on a herd of 35 cows with negative results MLLE A DUSSEAU A new durelloid hybrid strain resulting from the crossing of two *Triticum vulgare* PIERRE GAVAUDAN The diffuse vital staining of flagella and the chemical affinities of the cytoplasm and of its various constituents A GIROUD, C P LEBLOND and M GIROUX Vitamin C in the ovary and the yellow body Results of histological studies based on the reaction of ascorbic acid with silver nitrate P PORTIER and MLLE A RAFFY The mechanism of the death of birds the plumage of which is impregnated with hydrocarbons In the normal state the plumage of birds acts as a screen against losses of heat even in a prolonged dive under water near 0° C These heat insulating properties are lost when the feathers are covered with oil and this is the cause of death MLLE G COUSIN: The normal fecundity and characters of the hybrids resulting from crossing two species of grasshoppers, *Achæta campestris* and *A bimaculata* G DELAMARE Numerical variations of some primary sinusoids of the body of the Spirochetidæ

MELBOURNE

Royal Society of Victoria, December 14 W J HARRIS The eastern boundary of the Bendigo gold field A number of traverses across the eastern portion of the Bendigo goldfield show that the Lower Ordovician rocks (mostly Lancefieldian) near the east of the Bendigo city area, end abruptly and are succeeded farther to the east by beds which are uniformly much younger (Darriwilian) The break in the normal succession has been traced for a distance of about fourteen miles and is attributed to a fault named the Whitelaw fault, which runs almost parallel to the strike of the bed rock N 15° W The presence of the Darriwilian non auriferous beds accounts for the absence of profitable gold mining east of the line indicated F A SINGLETON and NELLY HOOPER WOODS On the occurrence of the pelecypod genus *Miltha* in the Australian Tertiary The Tertiary pelecypod, *Dosinia grandis*, Hooper Woods, from a boring near Adelaide, South Australia, is redescribed, refigured and transferred to *Miltha* (*Milthoidea*) in the family Lucinidæ A new subspecies, *flindersensis*, is described and figured from a boring on Flinders Island, Tasmania B J GRIEVE The isolation of the organism causing crown gall on almond trees in Victoria The galls have been shown to be related to the presence of bacteria The causal organism has been isolated in pure culture and has been shown to be identical with *Bacterium tumefaciens* Sm and T R B WITHERS and R A KEBLE The Palæozoic star fishes of Victoria This contribution comprises the Palæozoic star fishes of Victoria and nearly all those of Australia, they are wholly of Silurian age Ten new species have been described Several of the genera represented are new to Victoria, one of the most interesting is *Hudsonaster*, which is regarded as a somewhat primitive type and is only recorded from Ordovician beds elsewhere

VIENNA

Academy of Sciences, December 7 HERBERT HABERLANDT, BERTA KARLIK and KARL PRZIBRAM Synthesis of the blue fluorescence of fluorite Examination of a number of mixtures of fluorite with small proportions of other substances shows that the fluorescence exhibits blue bands only when a rare earth metal, most probably europium, is present After being heated and exposed to radium radiation calcium fluoride, either pure or containing 0 1 per cent of cerium, praseodymium, neodymium or samarium, gives no blue bands, which, however, appear when either impure samarium (containing europium) or pure europium is added (see also NATURE, 133, 99, Jan 20, 1934) ALEXANDER KÖHLER and HERBERT HABERLANDT Luminescence of apatite and other phosphates As with fluorite, so also with many apatites, either in the natural state or after heating, the occurrence of lines in the fluorescence spectrum affords a sensitive means of detecting rare earths Certain other phosphates may be examined similarly GEORG STETTER (1) Process of charging in the ionisation chamber (2) Choice of the grid resistance for a highly sensitive amplifier GUSTAV ORTNER and GEORG STETTER (1) Choice of the coupling element in making an amplifier with low time constant (2) Experiments on atom-disintegration with radium B+C as source of radiation (1) By the procedure described processes of nuclei transformation occurring when RaB+C is used as source of radiation may in spite of the presence of β and γ rays be recorded electrically with the same reliability as when polonium is used **Georg Koller** and **Adolf Klein** Saxatilic acid On the basis of the known chemical behaviour together with new data a structural formula for this acid is proposed **Kasimir Graff** (1) Colorimetric and photometric observations on δ Cephei and η Aquilæ The spectral changes of these two stars show also in the visual colour and are readily detectable with a colorimeter The colour curve of δ Cephei is very similar to but not quite synchronous with the light curve With η Aquilæ however larger deviations occur (2) Regularities in the change in colour of stars on the horizon The excess colour of stars on the horizon observed in Majorca is related linearly to the path of the rays in the homogeneous atmosphere **Rudolf Grill** Oligocene and miocene in the Gallneukirchen basin east of Linz on the Danube and the neighbouring regions **Wolfgang Holzer** Action of rapid electrical vibrations on electrolyte solutions in relation to biological effects of short waves

December 14 **Stefan Pelz** Crystal photo effect in coloured rock salt **A Skrabal** Unstable intermediate products and classical chemical mechanics In investigations on chemical kinetics it is often necessary to decide from a given scheme of reactions in which unstable reactants take part the actual gross reactions occurring and their velocity equations A method of solving this problem based on classical chemical mechanics is now given **K W F Kohlrausch** and **A Pongratz** Studies on the Raman effect (31) Raman spectrum of organic substances (polysubstituted benzenes) Each of the four spectra for the molecular types C_6H_5X and CH_3 C_6H_4X (X in the ortho meta or para position) is analysed for the cases where X is NH_2 OH F CH_3 CN Cl Br or I

Forthcoming Events

[*Meetings marked with an asterisk are open to the public*]

Monday April 23

Victoria Institute at 4 30—Sir Charles Marston Bible and Spade

Royal Geographical Society at 5 30— Life in Hungary (film)

Tuesday April 24

Royal Society of Arts at 4 30—C F Strickland 'The Co operative Movement among African Races

Thursday April 26

Royal Society at 4 30—F W P Götz, A R Meetham and Dr G M B Dobson The Vertical Distribution of Ozone in the Atmosphere

Dr F P Bowden and Dr C P Snow Physico Chemical Studies of Complex Organic Molecules (1)

Dr F P Bowden and S D D Morris Physico Chemical Studies of Complex Organic Molecules (2)

London Mathematical Society at 5—(at Burlington House, W 1)—Discussion on Integral Functions Speakers Prof E C Titchmarsh, Dr E F Collingwood, Dr M L Cartwright Prof J M Whittaker A J Macintyre Prof J E Littlewood.

Worshipful Company of Armourers and Brasiers at 5 30—(in the Metallurgy Lecture Theatre Royal School of Mines Prince Consort Road, South Kensington)—Prof J H Andrew Alloy Steels (succeeding lectures on May 3 and 10) *

Institution of Electrical Engineers at 6—Prof J C M Lennan Electrical Phenomena at Extremely Low Temperatures (Twenty fifth Kelvin Lecture)

Friday April 27

Royal Institution at 9—J M Stagg 'The British Polar Year Expedition to Fort Rae N W Canada, 1932 33
